--------------	---------------------------------	-----

1.0 Project Overview

TransCanada Keystone Pipeline, L.P. (Keystone) is proposing to construct and operate a crude oil pipeline and related facilities from Hardisty, Alberta, Canada, to the Port Arthur and east Houston areas of Texas in the United States (US). The project, known as the Keystone XL Project (Project), will have a nominal capacity to deliver up to 900,000 barrels per day (bpd) of crude oil from an oil supply hub near Hardisty to existing terminals in Nederland near Port Arthur and ~~the Houston Ship Channel in Houston~~ Moore Junction in Harris County, Texas. The project will consist of three new pipeline segments plus additional pumping capacity on the Cushing Extension Segment of the Keystone Pipeline Project (Keystone Cushing Extension). The Steele City Segment of the Project extends from Hardisty, Alberta southeast to Steele City, Nebraska. The Gulf Coast Segment extends from Cushing, Oklahoma south to Nederland, Texas. The Houston Lateral extends from the Gulf Coast Segment, in Liberty County, Texas southwest to Moore Junction, Harris County, Texas near the Houston Ship Channel (**Figure 1.1-1**). In total, the Project will consist of approximately 1,707~~2~~ miles of new, 36-inch-diameter pipeline, consisting of about 327 miles in Canada and 1,380~~75~~ miles within the US. It will interconnect with the northern and southern termini of the previously approved 298-mile-long, 36-inch-diameter Keystone Cushing Extension. The Project is planned to be placed into service in phases. The Gulf Coast Segment ~~and the Houston Lateral are~~ is planned to be in service in 2011, ~~and t~~ The Steele City Segment and the Houston Lateral are ~~is~~ planned to be in service in 2012.

Figure 1.1-1 Keystone XL Project Route

1.1 Federal and Montana Permitting Processes

The Project will require the issuance of a Presidential Permit by the U.S. Department of State (DOS) to cross the US/Canada border. The proposed route also crosses federal lands managed by the Bureau of Land Management (BLM) that will require the issuance of a ROW grant. The issuance of the Presidential Permit and a ROW grant across federal lands are considered federal actions and, therefore, the Project is subject to environmental review pursuant to the National Environmental Policy Act (NEPA) (42 United States Code § 4321 et seq.). The DOS has been designated as the lead federal agency for NEPA compliance, with the BLM participating as a cooperating agency.

In Montana the Project requires a certificate under the Montana Major Facilities Siting Act (MFSA), which includes environmental review under the Montana Environmental Policy Act (MEPA). The Montana Department of Environmental Quality has indicated that it will also use the NEPA review document and process to satisfy its environmental review requirement under MEPA.

Keystone ~~has~~ submitted ~~ing~~ a MFSA application to the MDEQ, which includes an objective disclosure of beneficial and adverse environmental impacts resulting from the Project, as well as a set of reasonable alternatives. This risk assessment supplements the information in the MFSA application, disclosing potential environmental consequences that might occur in the unlikely event of a crude oil release from the Project.

2.0 Introduction

This report represents Keystone's evaluation of the risk of a pipeline disruption and its potential environmental consequences to support the MEPA process. This report focuses on the potential for spills during operations and the subsequent potential effects on sensitive resources and humans associated with major spills. Additional effects on public health and safety that could occur during project construction are discussed under other resource sections (e.g., air quality, water resources, transportation, land use, and aesthetics) within the Project's MFSA Application.

The purpose of this report is threefold. First, the report presents an assessment of potential effects resulting from the operation of the US portion of the Project that is sufficient for the purposes of MEPA. Second, the report provides a preliminary evaluation of potential risk for use during the pipeline's design phase, to facilitate the early selection of possible valve locations. Third, this report provides Keystone an initial basis for the development of emergency response planning and eventual incorporation of the Project into TransCanada's Integrity Management Program. Given these objectives, the analysis summarized within this report is intentionally conservative (i.e., overestimates risk). Keystone's expectation is that the spill frequencies and volumes presented in this analysis are not likely to occur, but are provided as a conservative framework to ensure agency decisions are based on knowledge of the potential range of effects as well as allowing Keystone to prepare for the worst-case scenarios in its emergency response preparations.

This report presents the results of a pipeline incident frequency and spill volume analysis based on Keystone's design and operations criteria and applies the resulting risk probabilities to an environmental consequence analysis that incorporates project-specific environmental data. Specifically, this report evaluates the risk of crude oil spills during pipeline operations, including contribution of natural hazards to spill risk, and the subsequent potential effects on humans and other sensitive resources, particularly high consequence areas (HCAs), that include designated populated areas, drinking water areas, and/or ecologically sensitive areas.

3.0 Incident Frequency-Spill Volume Study

Keystone conducted a project-specific incident¹ frequency and spill volume analysis for the US portion of the Project. The analysis conservatively estimated the frequency and volume of releases for five distinct and independent failure causes. The study quantitatively assessed spill potential for the entire pipeline utilizing publicly available historical incident data collected from Pipeline and Hazardous Materials Safety Administration (PHMSA) incident reports.

3.1 Incident Frequency

Incident frequencies were estimated from publicly available historical data (PHMSA 2008) and modified by segment-specific adjustment factors for the Project. Based on the available information, the study produced a conservative incident frequency of ~~0.000119~~0.000133 incidents per mile per year, equivalent to no more than one spill in ~~30-26~~ years for the 282 miles of the Project in Montana. For any 1-mile segment, this probability is equivalent to 1 spill every ~~8,400~~7,500 years.

While future events cannot be known with absolute certainty, incident frequencies can be used to estimate the number of events that might occur over a period of time. Actual frequency may differ from the predicted values of this analysis and Keystone believes that the actual number of incidents will be substantially lower than estimated for this report. In this regard, it should be noted that the number of spills on crude oil pipelines has substantially declined in recent years with the implementation of US Department of Transportation's (USDOT) Integrity Management Rule.

3.2 Spill Volume

For this analysis, maximum spill volumes were determined for a complete rupture of the Keystone XL pipeline, accounting for maximum throughput, time to isolate the leak (detection and system shutdown), and subsequent draindown from the affected pipeline segment. While Keystone has reported maximum spill volumes, actual incident data from the *Hazardous Liquid Pipeline Risk Assessment* (California State Fire Marshal 1993) indicate that spill volumes are significantly less than the maximum potential draindown volume. For example, in 50 percent of the cases, the actual spill volume represented less than 0.75 percent of the maximum potential draindown volume. In 75 percent of the cases, the actual spill volume represented less than 4.6 percent of the maximum draindown volume. Procedures to reduce spill volume, by reducing draindown and depressurizing, are not estimated or included in the analysis. If these procedures were included, they most likely would significantly reduce the predicted maximum spill volumes estimated for the Project, if a spill were to occur.

PHMSA's incident database (2008) demonstrates that Keystone's maximum spill volumes are highly conservative (i.e., overstate risk). Examination of the current PHMSA dataset (2002 to present) indicates that the vast majority of actual pipeline spills are relatively small, with 50 percent of the spills consisting of 3.0 barrels or less. In 85 percent of the cases, the spill volume was 100 barrels or less, and in over 95 percent of cases spill volumes were less than 1,000 barrels. Oil spills of 10,000 barrels or greater only occurred in 0.5 percent of cases. These data demonstrate that most pipeline spills are small and very large releases of 10,000 barrels or more are extremely uncommon.

¹ An "incident" refers to a variety of abnormal pipeline events that are reportable to the PHMSA, including the release of oil greater than 5 gallons; a release resulting in an explosion or fire; and accident resulting in human injuries requiring hospitalization; fatality; or property damage (including operator costs, such as product loss, emergency response, and cleanup costs) in excess of \$50,000.

Of the postulated maximum of one spill along the Project in Montana during a ~~30~~²⁶-year period, these PHMSA-derived spill volume statistics suggest that this one spill would have a 50 percent probability of being 3 barrels or less; 35 percent probability of being between 3 and 100 barrels; 10 percent probability of being between 100 and 1,000 barrels; 5 percent probability of being between 1,000 and 10,000 barrels; and a 0.5 percent probability of being more than 10,000 barrels².

² A barrel of oil equals 42 gallons.

4.0 Consequences of a Spill

4.1 Human Consequences

The risk associated with the operation of the Project can be compared with the general risks encountered in everyday life. Proposed actions that result in negligible additional risk from any cause are generally considered acceptable. The National Center for Health Statistics (Center for Disease Control 2003) overall average annual death rate for the general population in the US is approximately 830 per 100,000. The USDOT reports the historical average risk to the general population per year associated with all hazardous liquids transmission pipelines, such as the Project, is 0.004 in 100,000 (USDOT 2002). Therefore, the predicted risk of fatality to the public from incidents associated with the Project over and above the normal US death rate is negligible.

4.2 Environmental Consequences

The environmental risk posed by a crude oil pipeline is a function of: 1) the probability of an accidental release; 2) the probability of a release reaching an environmental receptor (e.g., waterbody, fish); 3) the concentration of the contamination once it reaches the receptor; and 4) the hazard posed by that concentration of crude oil to the receptor. Based on spill probabilities and estimated spill volumes, this environmental assessment determines the probability of exposure to environmental receptors and the probable impacts based on a range of potential concentrations.

4.2.1 Environmental Fate of Crude Oil Spills

4.2.1.1 Crude Oil Composition

The composition of crude oil varies widely, depending on the source and processing. Crude oils are complex mixtures of hundreds of organic (and a few inorganic) compounds. These compounds differ in their solubility, toxicity, persistence, and other properties that profoundly affect their impact on the environment. The effects of a specific crude oil cannot be thoroughly understood without taking its composition into account.

Crude oil expected to be transported by the Project is derived from the Alberta oil sands region in Canada. The oil extracted from the oil sands is called bitumen, which is highly viscous. In order for the bitumen to be transported by pipeline, it is either mixed with a diluent and is transported as diluted bitumen, or upgraded to synthetic crude oil before transportation. The precise composition of diluted bitumen and synthetic crude will vary by shipper and is considered proprietary information. Diluted bitumen is similar to other crude oils derived from various locations throughout the world, such as portions of California, Venezuela, Nigeria, and Russia. For the purposes of this analysis, transportation of two crude oil types will be assumed: diluted bitumen and synthetic crude. In general, the pipeline will contain segregated batches of these two products.

The primary classes of compounds found in crude oil are alkanes (hydrocarbon chains), cycloalkanes (hydrocarbons containing saturated carbon rings), and aromatics (hydrocarbons with unsaturated carbon rings). Most crude oils are more than 95 percent carbon and hydrogen, with small amounts of sulfur, nitrogen, oxygen, and traces of other elements. Crude oils contain lightweight straight-chained alkanes (e.g., hexane, heptane); cycloalkanes (e.g., cyclohexane); aromatics (e.g., benzene, toluene); cycloalkanes; and heavy aromatic hydrocarbons (e.g., polycyclic aromatic hydrocarbons [PAHs], asphaltines). Straight-chained alkanes are more easily degraded in the environment than branched alkanes. Cycloalkanes are extremely resistant to biodegradation. Aromatics (e.g., benzene, toluene, ethylbenzene, and xylenes [BTEx] compounds) pose the most potential for environmental concern. Because of their lower molecular weight, they are more soluble in water than alkanes and cycloalkanes.

4.2.1.2 Environmental Fate and Transport

Environmental processes that govern the fate of a crude oil spill include dispersion, evaporation, dissolution, sorption, photodegradation, and natural attenuation. Once released into the terrestrial environment, the crude oil will pool in low-lying areas. If left unattended, some lighter volatile constituents of the crude oil will evaporate into air over time, while other constituents will bind or leach into soils, or dissolve into water. Hydrocarbons that volatilize into the atmosphere are broken down by sunlight into smaller compounds. This process, referred to as photodegradation, occurs rapidly in air and the rate of photodegradation increases as molecular weight increases. If released onto soil, a portion of the crude oil will penetrate the soil as a result of the effects of gravity and capillary action. The rate of penetration will depend on the nature of the soil. Crude oil adheres to soil particles, limiting the spread of crude oil in soils. If released into water, crude oil will float to the water's surface. If crude oil is left on the water's surface over an extended period of time, some constituents within the oil will evaporate, other fractions will dissolve, and, eventually, some material may descend to the bottom as sedimentation.

Spreading of crude oil across soils is governed by slope, soil permeability, and, to a lesser extent, ambient temperature. Crude oil mobility in water increases with wind, stream velocity, and increasing temperature. Most crude oils spread across surface waters at a rate of 100 to 300 meters per hour. Surface ice will greatly reduce the spreading rate of oil across a waterbody. Spreading reduces the bulk quantity of crude oil present in the immediate vicinity of the spill but increases the spatial area within which adverse effects may occur. Thus crude oil in flowing, as opposed to contained, waterbodies will be less concentrated in any given location, but may cause impacts, albeit reduced in intensity, over a much larger area. Spreading and thinning of spilled crude oil also increases the surface area of the slick, thus enhancing surface dependent fate processes such as evaporation, degradation, and dissolution.

Dispersion of crude oil across water increases with increasing surface turbulence. The dispersion of crude oil into water may serve to increase the surface area of crude oil susceptible to dissolution and degradation processes and thereby limit the potential for physical impacts.

Over time, evaporation is the primary mechanism of loss for low molecular weight constituents and light oil products. As lighter components evaporate, remaining crude oil becomes denser and more viscous. Evaporation thus tends to reduce crude oil toxicity but enhances crude oil persistence. In field trials, bulk evaporation of Alberta crude oil accounted for an almost 50 percent reduction in volume over a 12-day period, while the remaining oil was still sufficiently buoyant to float on the water's surface (Shiu et al. 1988). Evaporation increases with increased spreading of a slick, increased temperature, and increased wind and wave action.

Dissolution of crude oil in water is not a significant process controlling the crude oil's fate in the environment, since most components of oils are relatively insoluble (Neff and Anderson 1981). Moreover, overall solubility of crude oils tend to be less than their constituents since solubility is limited to the partitioning between oil and water interface and individual compounds are often more soluble in oil than in water, thus they tend to remain in the oil. Nevertheless, dissolution is one of the primary processes affecting the toxic effects of a spill, especially in confined waterbodies. Dissolution increases with decreasing molecular weight, increasing temperature, decreasing salinity, and increasing concentrations of dissolved organic matter. Greater photodegradation also tends to enhance the solubility of crude oil in water.

In water, heavy molecular weight hydrocarbons will bind to suspended particulates, and this process can be significant in highly turbid or eutrophic waters. Organic particles (e.g., biogenic material) in soils or suspended in water tend to be more effective at sorbing oils than inorganic particles (e.g., clays). Sorption processes and sedimentation reduce the quantity of heavy hydrocarbons present in the water column and available to aquatic organisms. However, these processes also render hydrocarbons less susceptible to degradation. Sedimented oil tends to be highly persistent and can cause shoreline impacts.

Photodegradation of crude oil in terrestrial and aquatic systems increases with greater solar intensity. It can be a significant factor controlling the disappearance of a slick, especially of lighter oil constituents; but it will be less important during cloudy days and winter months. Photodegraded crude oil constituents tend to be more soluble and more toxic than parent compounds. Extensive photodegradation, like dissolution, may thus increase the biological impacts of a spill event.

In the immediate aftermath of a crude oil spill, natural biodegradation of crude oil will not tend to be a significant process controlling the fate of spilled crude oil in environments previously unexposed to oil. Microbial populations must become established before biodegradation can proceed at any appreciable rate. Also, prior to weathering (i.e., evaporation and dissolution of light-end constituents), oils may be toxic to the very organisms responsible for biodegradation and high molecular weight constituents tend to be resistant to biodegradation. Biodegradation is nutrient and oxygen demanding and may be precluded in nutrient-poor aquatic systems. It also may deplete oxygen reserves in closed waterbodies, causing adverse secondary effects to aquatic organisms.

With time, however, microorganisms capable of consuming crude oil generally increase in number and the biodegradation process naturally remediates the previously contaminated soil. The biodegradation process is enhanced as the surface area of spilled oil increases (e.g., by dispersion or spreading). Biodegradation has been shown to be an effective method of remediating soils and sediments contaminated by crude oil.

Overall, the environmental fate of crude oil is controlled by many confounding factors and persistence is difficult to predict with great accuracy. Major factors affecting the environmental fate include spill volume, type of crude oil, dispersal rate of the crude oil, terrain, receiving media, and weather. Once released, the physical environment largely dictates the environmental persistence of the spilled material. Along the Project route, the primary aquatic habitats of concern include low gradient streams, rivers, and small intermittent ponds. Wetlands also occur along the proposed pipeline route. Estimates of the length of time materials could persist at potentially acute concentrations vary depending on the speed and success of emergency containment and cleanup, the size of spill, and environmental conditions. In warm summer months, the acutely toxic volatile components of crude oil will evaporate quickly, and a relatively small release into a high gradient stream would be expected to rapidly dissipate. In contrast, crude oil released into a small stream in winter could become trapped under pockets of ice and, thus, persist longer.

4.2.2 Environmental Impacts

An evaluation of the potential impacts resulting from the accidental release of crude oil into the environment is discussed by environmental resource below.

4.2.2.1 Soils

Because pipelines are buried, soil absorption of spilled crude oil could occur, thus impacting the soils. Subsurface releases to soil tend to disperse slowly and are generally located within a contiguous and discrete area, often limited to the less consolidated soils (lower soil bulk density) within the pipeline trench. Effects to soils can be quite slow to develop, allowing time for emergency response and cleanup actions to mitigate effects to potential receptors.

In the event of a spill, a portion of the released materials would enter the surrounding soil and disperse both vertically and horizontally in the soil. The extent of dispersal would depend on a number of factors, including speed and success of emergency containment and cleanup, size and rate of release, topography of the release site, vegetative cover, soil moisture, bulk density and soil porosity. High rates of release from the buried pipeline would result in a greater likelihood that released materials would escape the trench and reach the ground surface.

If a release were to occur in sandy soils frequently encountered along the Project route, it is likely that the horizontal and vertical extent of the contamination would be greater than in areas containing more organic

soils. Crude oil released into sandy soils would likely become visible to aerial surveillance due to product on the soils surface or discoloration of nearby vegetation. If present, soil moisture and moisture from precipitation would increase the dispersion and migration of crude oil.

The vast majority of the Project is located in relatively flat or modestly rolling terrain. In these areas, the oil would generally begin dispersing horizontally within the pipeline trench, and with sufficient spill volume or flow, then the oil could move out of the trench onto the soils surface, generally moving towards and breaking the soil surface in low lying areas. If the spill were to occur on a steep slope where trench breakers had been installed during construction, then crude oil would pool primarily within the trench behind any trench breakers. If sufficient volume existed, the crude oil would breach the soil's surface as it extended over the top of the trench breaker. In either case, once on the soil's surface, the release would be more apparent to leak surveillance patrols.

Both on the surface and in the subsurface, rapid attenuation of light, volatile constituents (due to volatilization) would quickly reduce the total volume of crude oil, while heavier constituents would be more persistent. Except in rare cases of high rate and high total volume releases with environmental settings characterized by steep topography or karst terrain, soil impacts would be confined to a relatively small, contiguous, and easily defined area, facilitating cleanup and remediation. Within a relatively short time, lateral migration would generally stabilize. Downward vertical migration would begin at the onset of a spill, with rates governed by soil permeability. For example, in soils with moderately high permeability, water may penetrate 2.5 inches per hour, while penetration rates for soils of low permeability may occur at 0.05 inch/hour. Crude oil is more viscous than water, therefore permeability of crude oil would be slower than water.

In accordance with Federal and state regulations, Keystone would be responsible for cleanup of contaminated soils and would be required to meet applicable cleanup levels. In Montana, the soil cleanup level for benzene from petroleum hydrocarbon releases is 0.04 part per million (ppm).

It is difficult to estimate the volume of soil that might be contaminated in the event of a spill. Site-specific environmental conditions (e.g., soil type, weather conditions) and release dynamics (e.g., leak rate, leak duration) would result in substantially different surface spreading and infiltration rates, which in turn, affect the final volume of affected soil to be remediated. Based on historical data (PHMSA 2008), soil remediation involved 100 cubic yards of soil or less at the majority of spill sites where soil contamination occurred, and only 3 percent of the spill sites required remediation of 10,000 cubic yards or more (PHMSA 2008).

4.2.2.2 Vegetation and Soil Ecosystems

Crude oil released to the soil's surface could potentially produce localized effects on plant populations. Terrestrial plants are much less sensitive to crude oil than aquatic species. The lowest toxicity threshold for terrestrial plants found in the U.S. Environmental Protection Agency (USEPA) ECOTOX database (USEPA 2001) was 18.2 ppm for benzene, higher than the 7.4 ppm threshold for aquatic species and the 0.005 ppm threshold for human drinking water. Similarly, available data from the USEPA database indicate that earthworms also are less sensitive than aquatic species (toxicity threshold was greater than 1,000 ppm). If concentrations were sufficiently high, crude oil in the root zone could harm individual plants and organisms.

Release of crude oil could result in the contamination of soils (see Section 4.2.2.1, Soils, above). Keystone would be responsible for cleanup of contaminated soils. Once remedial cleanup levels were achieved in the soils, no adverse or long-term impacts to vegetation would be expected.

4.2.2.3 Wildlife

Spilled crude oil can affect organisms directly and indirectly. Direct effects include physical processes, such as oiling of feathers and fur, and toxicological effects, which can cause sickness or mortality. Indirect effects are less conspicuous and include habitat impacts, nutrient cycling disruptions, and alterations in ecosystem relationships. The magnitude of effects varies with multiple factors, the most significant of which include the

amount of material released, the size of the spill dispersal area, the type of crude oil spilled, the species assemblage present, climate, and the spill response tactics employed.

Wildlife, especially birds and shoreline mammals, are typically among the most visibly affected organisms in any crude oil spill. Effects of crude oil can be differentiated into physical (mechanical) and toxicological (chemical) effects. Physical effects result from the actual coating of animals with crude oil, causing reductions in thermal insulative capacity and buoyancy of plumage (feathers) and pelage (fur).

Crude oil released to the environment may cause adverse biological effects on birds and mammals via inhalation or ingestion exposure. Ingestion of crude oil may occur when animals consume oil-contaminated food, drink oil-contaminated water, or orally consume crude oil during preening and grooming behaviors.

Potential adverse effects could result from direct acute exposure. Acute toxic effects include drying of the skin, irritation of mucous membranes, diarrhea, narcotic effects, and possible mortality. While releases of crude oil may have an immediate and direct effect on wildlife populations, the potential for physical and toxicological effects attenuates with time as the volume of material diminishes, leaving behind more persistent, less volatile, and less water-soluble compounds. Although many of these remaining compounds are toxic and potentially carcinogenic, they do not readily disperse in the environment and their bioavailability is low, and therefore, the potential for impacts is low.

Unlike aquatic organisms that frequently cannot avoid spills in their habitats, the behavioral responses of terrestrial wildlife may help reduce potential adverse effects. Many birds and mammals are mobile and generally will avoid oil-impacted areas and contaminated food (Sharp 1990; Stubblefield et al. 1995). In a few cases, such as cave-dwelling species, organisms that are obligate users of contaminated habitat may be exposed. However, most terrestrial species have alternative, unimpacted habitat available, as will often be the case with localized spills (in contrast to large-scale oil spills in marine systems), therefore, mortality of these species would be limited (Stubblefield et al. 1995).

Indirect environmental effects of spills can include reduction of suitable habitat or food supply. Primary producers (e.g., algae and plants) may experience an initial decrease in primary productivity due to physical effects and acute toxicity of the spill. However, these effects tend to be short-lived and a decreased food supply is not considered to be a major chronic stressor to herbivorous organisms after a spill. If mortality occurs to local invertebrate and wildlife populations, the ability of the population to recover will depend upon the size of the impact area and the ability of surrounding populations to repopulate the area.

4.2.2.4 Water Resources

Crude oil could be released to water resources if the pipeline is breached or leaks occur. As part of project planning and in recognition of the environmental sensitivity of waterbodies, the Project routing process attempted to minimize the number waterbodies crossed, including groundwater aquifers. Furthermore, valves have been strategically located along the Project route to help reduce the amount of crude oil that could potentially spill into waterbodies, if such an event were to occur. The location of valves, spill containment measures, and implementing actions in the Project Emergency Response Plan would mitigate adverse effects to both surface water and groundwater.

Groundwater

Multiple groundwater aquifers underlie the proposed Project. Vulnerability of these aquifers is a function of the depth to groundwater and the permeability of the overlying soils. While routine operation of the Project would not affect groundwater, there is the possibility that a release could migrate through the overlying surface materials and enter a groundwater system.

In general, the potential for groundwater contamination following a spill would be more probable in locations where a release into or on the surface of soils has occurred:

- Where a relatively shallow water table is present (as opposed to locations where a deeper, confined aquifer system is present);
- Where soils with high permeability are present throughout the unsaturated zone; and
- Where, in cooperation with federal and state agencies, the PHMSA (in cooperation with the US Geological Service [USGS] and other agencies) has identified groundwater resources that are particularly vulnerable to contamination. These resources are designated by PHMSA as High Consequence Areas (HCAs; Section 4.3.2).

Depending on soil properties, the depth to groundwater, and the amount of crude oil in the unsaturated zone, localized groundwater contamination can result from the presence of free crude oil and the migration of its dissolved constituents. Crude oil is less dense than water and would tend to form a floating pool after reaching the groundwater surface. Movement of crude oil is generally quite limited due to adherence with soil particles, groundwater flow rates, and natural attenuation (i.e., microbial degradation) (Freeze and Cherry 1979; Fetter 1993). Those compounds in the crude oil that are soluble in water will form a larger, dissolved “plume.” This plume would tend to migrate laterally in the direction of groundwater flow. Movement of dissolved constituent typically extends for greater distances than movement of pure crude oil in the subsurface, but is still relatively limited. The flow velocity of dissolved constituents would be a function of the groundwater flow rate and natural attenuation, with the dissolved constituents migrating more slowly than groundwater.

Unlike chemicals with high environmental persistence (e.g., trichloroethylene, pesticides), the aerial extent of the dissolved constituents will stabilize over time due to natural attenuation processes. Natural biodegradation through metabolism by naturally occurring microorganisms is often an effective mechanism for reducing the volume of crude oil and its constituents. Natural attenuation will reduce most toxic compounds into non-toxic metabolic byproducts, typically carbon dioxide and water (Minnesota Pollution Control Agency 2005). Field investigations at historical crude oil release sites indicate the migration of dissolved constituents typically stabilize within several hundred feet of the crude oil source area, depending on groundwater flow velocity and other site-specific hydrogeologic factors (USGS 1998; Charbeneau 2003). Over a longer period, the area of the contaminant plume may begin to reduce due to natural biodegradation. Removal of crude oil contamination will eliminate the source of dissolved constituents impacting the groundwater.

Most crude oil constituents are not water soluble. For those constituents that are water soluble (e.g., benzene) the dissolved concentration is not controlled by the amount of oil in contact with the water, but by the concentration of the specific constituent in the oil (Charbeneau et al. 2000; Charbeneau 2003; Freeze and Cherry 1979). Studies of 69 crude oils found that benzene was the only aromatic or PAH compound tested that is capable of exceeding groundwater protection values for drinking water (i.e., maximum contaminant levels [MCLs] or Water Health Based Limits) (Kerr et al. 1999 as cited in O'Reilly et al. 2001).

If exposure to humans or other important resources would be possible from a release into groundwater, then regulatory standards, such as drinking water criteria (MCL) would mandate the scope of remedial actions, timeframe for remediation activities, and cleanup levels. The promulgated drinking water standards for humans vary by several orders of magnitude for crude oil constituents. For human health protection, the national MCL is an enforceable standard established by the USEPA and is designed to protect long-term human health. Of the various crude oil constituents, benzene has the lowest national MCL at 0.005 ppm³ and, therefore, it was used to evaluate impacts on drinking water supplies, whether from surface water or groundwater.

However, response and remediation efforts have the potential for appreciable adverse effects from construction/cleanup equipment. If no active remediation activities were undertaken, natural biodegradation and attenuation ultimately would allow a return to preexisting conditions in both soil and groundwater.

³ Montana also uses the national MCL value of 0.005 ppm.

Depending on the amount of crude oil reaching the groundwater and natural attenuation rates, this would likely require up to tens of years. Keystone will utilize the most appropriate cleanup procedure as determined in cooperation with the applicable federal and state agencies.

Attenuation mechanisms that retard the movement of contaminants include dispersion, sorption, volatilization, abiotic chemical degradation, and biological degradation. The extent to which any of these mechanisms would retard contaminant movement at a given location depends upon site-specific conditions. In general, crude oil in groundwater tends to biodegrade as described for soil releases. Even in the case of large released volumes and floating free crude oil, dispersive forces become balanced with biodegradation and attenuation mechanisms, establishing degradation equilibrium. The typical result is a relatively limited zone of impact, typically 200 meters or less downgradient (USGS 1998). Over time, these natural degradation mechanisms, along with other natural attenuation mechanisms, including dispersion, result in the removal and/or destruction of crude oil materials; both in groundwater, and in overlying impacted soils. Observed degradation rates indicate this process would typically occur in timeframes measured in tens of years, depending on the concentration of crude oil in the groundwater.

Flowing Surface Waters

The PHMSA, in cooperation with various federal and state agencies, has identified surface water resources that are particularly vulnerable to contamination. These surface water resources are designated as HCAs (Section 4.3.2). Broadly, this report evaluated impacts to downstream drinking water sources by comparing projected surface water benzene concentrations with the national MCL for benzene. Like other pipelines already in existence, the Project will cross hundreds of perennial, intermittent, and ephemeral streams. Rather than evaluate the risk to each waterbody crossed by the Project, this risk assessment evaluated categories of streams, based on the magnitude of streamflow and stream width. **Table 4-1** summarizes the stream categories used for the assessment and identifies several representative streams within these categories.

Table 4-1 Stream Categories

	Streamflow (cubic feet per second; cfs)	Stream Width (feet)	Representative Streams
Low Flow Stream	10 – 100	<50	Many unnamed intermittent tributaries, Bear Creek
Lower Moderate Flow Stream	100 – 1,000	50 – 500	Upper Sevenmile Creek, Lone Tree Creek
Upper Moderate Flow Stream	1,000 – 10,000	500 – 1,000	Yellowstone River
High Flow Stream	>10,000	1,000 – 2,500	Missouri River

The following highly conservative assumptions were used for this analysis: 1) the entire volume of a spill was released directly into a waterbody; 2) complete, instantaneous mixing occurred; and 3) the entire benzene content was solubilized into the water column. While none of these assumptions would naturally occur, these were extremely conservative assumptions designed to over-estimate potential effects for planning purposes. It does not reflect Keystone's expectations of actual effects in the unlikely event of a spill.

A 1-hour release period for the entire spill volume was assumed in order to maximize the product concentration in water. The estimated benzene concentrations were then compared with the human health drinking water MCL for benzene (**Tables 4-2 and 4-3**). Based on these ultra-conservative assumptions, results suggest that most spills that enter a waterbody could result in exceedence of the national MCL for benzene. Although the assumptions used are highly conservative and, thus, overestimate potential benzene water concentrations, the analysis indicates the need for rapid notification of managers of municipal water intakes

downstream of a spill so that any potentially affected drinking water intakes could be closed to bypass river water containing crude oil.

In addition to evaluating a spill to generic flowing water, the potential for impacts to any specific waterbody also were evaluated. To do this, the occurrence interval for a spill at any one representative stream within one of the four stream categories reflected in Table 4-1 was calculated based on spill probabilities generated from the PHMSA database. To be conservative, a 500-foot buffer on either side of the river was added to the crossing widths identified in **Table 4-1**. The occurrence intervals shown on **Tables 4-2** and **4-3** indicate the chance of a spill occurring at any specific waterbody is very low. Conservative occurrence intervals for a spill at any representative stream within any of the stream categories ranged from ~~about~~ approximately 23,000 ~~25,000~~ years for a large waterbody to over ~~999~~ 840,000 years for a small waterbody (less likely to occur in any single small waterbody than any single large waterbody). If any release did occur, it is likely that the total release volume of a spill likely would be 3 barrels or less based on historical spill volumes.

In summary, while a release of crude oil directly into any given waterbody would likely cause an exceedence of drinking water standards, the frequency of such an event would be extremely low. Nevertheless, streams and rivers with downstream drinking water intakes represent sensitive environmental resources and could be temporarily impacted by a crude oil release. Keystone's Emergency Response Plan contains provisions for protecting and mitigating potential impacts to drinking water.

Aquatic Organisms

The concentration of crude oil constituents in an actual spill would vary both temporally and spatially in surface water; however, localized toxicity could occur from virtually any size of crude oil spill. **Table 4-4** summarizes the acute toxicity values (USEPA 2000) of various crude oil hydrocarbons to a broad range of freshwater species. Acute toxicity refers to the death or complete immobility of an organism within a short period of exposure. The LC₅₀ is the concentration of a compound necessary to cause 50 percent mortality in laboratory test organisms. For aquatic biota, most acute LC₅₀ for monoaromatics range between 10 and 100 ppm. LC₅₀ for the polyaromatic naphthalene were generally between 1 and 10 ppm, while LC₅₀ values for anthracene were generally less than 1 ppm.

Table 4-4 shows fish are among the most sensitive aquatic biota, while aquatic invertebrates generally have intermediate sensitivities, and algae and bacteria tend to be the least sensitive. Nevertheless, even when major fish kills have occurred as a result of oil spills, population recovery has been observed, and long-term changes in fish abundance have not been reported. Benthic (bottom-dwelling) aquatic invertebrates tend to be more sensitive than algae, but are equally or less sensitive than fish. Planktonic (floating) species tend to be more sensitive than most benthic insects, crustaceans, and molluscs.

In aquatic environments, toxicity is a function of the concentration of a compound necessary to cause toxic effects combined with the compound's water solubility. For example, a compound may be highly toxic, but if it is not very soluble in water then its toxicity to aquatic biota is relatively low. The toxicity of crude oil is dependent of the toxicity of its constituents. As an example, **Table 4-5** summarizes the toxicity of various crude oil hydrocarbons to the zooplankton, *Daphnia magna*. The relative toxicity of decane is much lower than for benzene or ethylbenzene because of the comparatively low solubility of decane. Most investigators have concluded that the acute toxicity of crude oil is related to the concentrations of relatively lightweight aromatic constituents, particularly benzene.

Comparison of Estimated Benzene Concentrations with the Benzene MCL Resulting from a Diluted Bitumen Spill

Benzene MCL (ppm)	Stream Flow Rate (cfs)	Product Released							
		Very Small Spill: 3 barrels		Small Spill: 50 barrels		Moderate Spill: 1,000 barrels		Large Spill: 10,000 barrels	
		Benzene Conc. (ppm)	Occurrence Interval (years)	Benzene Conc. (ppm)	Occurrence Interval (years)	Benzene Conc. (ppm)	Occurrence Interval (years)	Benzene Conc. (ppm)	Occurrence Interval (years)
0.005	10	0.652	<u>75,618</u> 84,513	10.9	<u>126,029</u> 140,855	218	<u>252,059</u> 281,710	2175	<u>840,196</u> 939,033
0.005	100	0.065	<u>52,932</u> 59,159	1.09	<u>88,221</u> 98,598	21.8	<u>176,441</u> 197,197	218	<u>588,137</u> 657,323
0.005	1,000	0.007	<u>39,699</u> 44,369	0.109	<u>66,165</u> 73,949	2.18	<u>132,331</u> 147,898	21.8	<u>441,103</u> 492,992
0.005	10,000	0.0007	<u>22,685</u> 25,354	0.0109	<u>37,809</u> 42,256	0.218	<u>75,618</u> 84,513	2.18	<u>252,059</u> 281,710

that the most probable spill volume would be 3 barrels or less. However, this entire analysis is based on conservative incident frequencies and volumes calculated using the 10,000 barrel spill volume, which overestimates the proportion of larger spills. Consequently, the assessment is conservative in its evaluation on the magnitude of environmental impacts.

The analysis is based on release of benzene into water over a 1-hour period with uniform mixing conditions.

The analysis is based on a 0.15 percent by weight benzene content of the transported material (www.crudeoilmonitor.ca May 2008 Summary).

The analysis is based on estimated benzene concentrations that could exceed the benzene MCL of 0.005 ppm.

The analysis is based on an overall predicted incident frequency of ~~0.000119~~0.000133 incident/mile*year, projected frequencies of each spill volume, and estimated stream flow rates. For flow streams that are greater than widths of lower flow streams, with more distance where an incident might occur. This results in a greater predicted frequency for corresponding lower occurrence interval.

Comparison of Estimated Benzene Concentrations with the Benzene MCL Resulting from a Synthetic Crude Spill

Benzene MCL (ppm)	Stream Flow Rate (cfs)	Product Released							
		Very Small spill: 3 barrels		Moderate spill: 50 barrels		Large spill: 1,000 barrels		Very Large spill: 10,000 barrels	
		Benzene Conc. (ppm)	Occurrence Interval (years)	Benzene Conc. (ppm)	Occurrence Interval (years)	Benzene Conc. (ppm)	Occurrence Interval (years)	Benzene Conc. (ppm)	Occurrence Interval (years)
0.005	10	<u>0.00113</u>	<u>75,618</u> <u>84,513</u>	<u>1.34</u> <u>2.2</u>	<u>126,029</u> <u>140,855</u>	<u>26.94</u> <u>3.5</u>	<u>252,059</u> <u>281,710</u>	<u>268.84</u> <u>34.9</u>	<u>840,196</u> <u>939,033</u>

¹ Indicates no value was available in the database.

Note: Data summarize conventional acute toxicity endpoints from USEPA's ECOTOX database. When several results were available for a given species, the geometric mean of the reported LC₅₀ values was calculated.

Table 4-5 Acute Toxicity of Crude Oil Hydrocarbons to *Daphnia magna*

Compound	48-hr LC ₅₀ (ppm)	Optimum Solubility (ppm)	Relative Toxicity
Hexane	3.9	9.5	2.4
Octane	0.37	0.66	1.8
Decane	0.028	0.052	1.9
Cyclohexane	3.8	55	14.5
methyl cyclohexane	1.5	14	9.3
Benzene	9.2	1,800	195.6
Toluene	11.5	515	44.8
Ethylbenzene	2.1	152	72.4
p-xylene	8.5	185	21.8
m-xylene	9.6	162	16.9
o-xylene	3.2	175	54.7
1,2,4-trimethylbenzene	3.6	57	15.8
1,3,5-trimethylbenzene	6	97	16.2
Cumene	0.6	50	83.3
1,2,4,5-tetramethylbenzene	0.47	3.5	7.4
1-methylnaphthalene	1.4	28	20.0
2-methylnaphthalene	1.8	32	17.8
Biphenyl	3.1	21	6.8
Phenanthrene	1.2	6.6	5.5
Anthracene	3	5.9	2.0
9-methylanthracene	0.44	0.88	2.0
Pyrene	1.8	2.8	1.6

Note: The LC₅₀ is the concentration of a compound necessary to cause 50 percent mortality in laboratory test organisms within a predetermined time period (e.g., 48 hours) (USEPA 2000).

Relative toxicity = optimum solubility/LC₅₀.

While lightweight aromatics such as benzene tend to be water soluble and relatively toxic, they also are highly volatile. Thus, most or all of the lightweight hydrocarbons accidentally released into the environment evaporate, and the environmental persistence of crude oil tends to be low. High molecular weight aromatic compounds, including PAHs, are not very water-soluble and have a high affinity for organic material. Consequently, these compounds, if present, have limited bioavailability, which render them substantially less toxic than more water-soluble compounds (Neff 1979). Additionally, these compounds generally do not accumulate to any great extent because these compounds are rapidly metabolized (Lawrence and Weber 1984; West et al.1984). There are some indications, however, that prolonged exposure to elevated

concentrations of these compounds may result in a higher incidence of growth abnormalities and hyperplastic diseases in aquatic organisms (Couch and Harshbarger 1985).

Significantly, some constituents in crude oil may have greater environmental persistence than lightweight compounds (e.g., benzene), but their limited bioavailability renders them substantially less toxic than other more soluble compounds. For example, aromatics with four or more rings are not acutely toxic at their limits of solubility (Muller 1987). Based on the combination of toxicity, solubility, and bioavailability, benzene was determined to drive toxicity associated with potential crude oil spills.

Table 4-6 summarizes chronic toxicity values (most frequently measured as reduced reproduction, growth, or weight) of benzene to freshwater biota. Chronic toxicity from other oil constituents may occur, however, if sufficient quantities of crude oil are continually released into the water to maintain elevated concentrations.

Table 4-6 Chronic Toxicity of Benzene to Freshwater Biota

Taxa	Test species	Chronic Value (ppm)
Fish	Fathead minnow (<i>Pimephales promelas</i>)	17.2 *
	Guppy (<i>Poecilia reticulata</i>)	63
	Coho salmon (<i>Oncorhynchus kitsutch</i>)	1.4
Amphibian	Leopard frog (<i>Rana pipens</i>)	3.7
Invertebrate	Zooplankton (<i>Daphnia</i> spp.)	>98
Algae	Green algae (<i>Selenastrum capricornutum</i>)	4.8 *

Note: Test endpoint was mortality unless denoted with an asterisk (*). The test endpoint for these studies was growth.

The potential impacts to aquatic organisms of various-sized spills to waterbodies were modeled assuming the benzene content within each type of crude oil completely dissolved in the water. The benzene concentration was predicted based on amount of crude oil spilled and streamflow. The estimated benzene concentrations were compared to conservative acute and chronic toxicity values for protection of aquatic organisms. For aquatic biota, the lowest acute and chronic toxicity thresholds for benzene are 7.4 ppm and 1.4 ppm, respectively, based on standardized trout toxicity tests (USEPA 2000). These toxicity threshold values are considered protective of acute and chronic effects to aquatic biota. Although trout are not found in many of the habitats crossed by the project, trout are among the most sensitive aquatic species and reliable acute and chronic trout toxicity data are available.

Tables 4-7 through 4-10 summarize the predicted acute and chronic toxicity to aquatic resources. Broadly, acute toxicity could potentially occur if substantial amounts of crude oil were to enter rivers and streams. If such an event were to occur within a small stream, aquatic species in the immediate vicinity and downstream of the rupture could be killed or injured. Chronic toxicity also could potentially occur in small and moderate sized streams and rivers. However, emergency response, containment, and cleanup efforts would help reduce the concentrations and minimize the potential for chronic toxicity. In comparison, relatively small spills (less than 50 barrels) into moderate and large rivers would not pose a major toxicological threat. In small to moderate sized streams and rivers, some toxicity might occur in localized areas, such as backwaters where concentrations would likely be higher than in the mainstream of the river.

Table 4-7 Comparison of Estimated Benzene Concentrations Following a Diluted Bitumen Spill to the Acute Toxicity Thresholds for Aquatic Life (7.4 ppm) for Streams Crossed by the Project

	Stream Flow Rate (cfs)	Acute Toxicity Threshold (ppm)	Product Released					
			Very Small Spill: 3 barrels		Small Spill: 50 barrels		Moderate Spill: 1,000 barrels	
			Benzene Conc. (ppm)	Occurrence Interval (years)	Benzene Conc. (ppm)	Occurrence Interval (years)	Benzene Conc. (ppm)	Occurrence Interval (years)
Low Flow Stream	10	7.4	0.7	<u>75,618</u> 84,513	10.9	<u>126,029</u> 140,855	217.5	<u>252,059</u> 284,710
Lower Moderate Flow Stream	100	7.4	0.07	<u>52,932</u> 59,159	1.1	<u>88,221</u> 98,598	21.7	<u>176,441</u> 197,197
Upper Moderate Flow Stream	1,000	7.4	0.007	<u>39,699</u> 44,369	0.1	<u>66,165</u> 73,949	2.2	<u>132,331</u> 147,898
High Flow Stream	10,000	7.4	0.0007	<u>22,685</u> 25,354	0.01	<u>37,809</u> 42,256	0.2	<u>75,618</u> 84,513

Notes:

- Historical data indicate that the most probable spill volume would be 3 barrels or less. However, this entire analysis is based on conservative incident frequencies and volumes calculated from worst-case spill volumes, which overestimates the proportion of larger spills. Consequently, the assessment is conservative in its evaluation on the magnitude of environmental consequences.
- Estimated proportion of benzene in the transported material is 0.15 percent (www.crudeoilmonitor.ca May 2008 Summary), and is assumed to be entirely water solubilized in the event of a spill. The resulting concentration was calculated by multiplying 0.15 percent of the total amount of material released divided by 1 hour of stream flow volume. The model assumes uniform mixing conditions.
- Benzene concentrations are compared against the acute toxicity threshold for benzene.
- Shading indicates concentrations that could potentially cause acute toxicity to aquatic species. The darkest shading represents high probability of acute toxicity (>10 times the toxicity threshold); lighter shading represents moderate probability of acute toxicity (1 to 10 times the toxicity threshold); and unshaded areas represent low probability of acute toxicity (<toxicity threshold).
- Occurrence intervals are based on an overall predicted incident frequency of ~~0.000119~~0.000133 incident/mile*year, projected frequencies of each spill volume, and estimated stream widths. Widths of higher flow streams are greater than widths of lower flow streams, with more distance where an incident might occur. This results in a greater predicted frequency for high flow streams and a corresponding lower occurrence interval.

Table 4-8

Product Released											
	Stream	Acute Toxicity Threshold (ppm)	Very Small Spill: 3 barrels		Small Spill: 50 barrels		Moderate Spill: 1,000 barrels		Large Spill: 10,000 barrels

Notes:

- Historical data indicate that the most probable spill volume would be 3 barrels or less. However, this entire analysis is based on conservative incident frequencies and volumes calculated from worst-case spill volumes, which overestimates the proportion of larger spills. Consequently, the assessment is conservative in its evaluation on the magnitude of environmental consequences.
- Estimated proportion of benzene in the transported material is 0.02-0.3 percent ([www.crudeoilmonitor.ca May 2008 Summary](http://www.crudeoilmonitor.ca/May%2008%20Summary)),⁷ and is assumed to be entirely water solubilized in the event of a spill. The resulting concentration was calculated by multiplying 0.03~~2~~ percent of the total amount of material released divided by 1 hour of stream flow volume. The model assumes uniform mixing conditions.
- Benzene concentrations are compared against the acute toxicity threshold for benzene.
- Shading indicates concentrations that could potentially cause acute toxicity to aquatic species. The darkest shading represents high probability of acute toxicity (>10 times the toxicity threshold); lighter shading represents moderate probability of acute toxicity (1 to 10 times the toxicity threshold); and unshaded areas represent low probability of acute toxicity (<toxicity threshold).
- Occurrence intervals are based on an overall predicted incident frequency of 0.00041190.000133 incident/mile*year, projected frequencies of each spill volume, and estimated stream widths. Widths of higher flow streams are greater than widths of lower flow streams, with more distance where an incident might occur. This results in a greater predicted frequency for high flow streams and a corresponding lower occurrence interval.

Table 4-9
Comparison of Estimated Diluted Bitumen Concentrations Following a Spill to the Chronic Toxicity Thresholds for Aquatic Life for Streams Crossed by the Project

Notes:

- Historical data indicate that the most probable spill volume would be 3 barrels or less. However, this entire analysis is based on conservative incident frequencies and volumes calculated from worst-case spill volumes, which overestimates the proportion of larger spills. Consequently, the assessment is conservative in its evaluation on the magnitude of environmental consequences.
- Estimated proportion of benzene in the transported material is 0.02-03 percent (www.crudeoilmonitor.ca May 2008 Summary), and is assumed to be entirely water solubilized in the event of a spill. The resulting concentration was calculated by multiplying 0.02-03 percent of the total amount of material released divided by 7 days of stream flow volume. The model assumes uniform mixing conditions.
- The chronic toxicity value for benzene is based on a 7-day toxicity value of 1.4 ppm for trout.
- Exposure concentrations were estimated over a 7-day period since the chronic toxicity value was based on a 7-day exposure.
- Shading indicates concentrations that could potentially cause chronic toxicity to aquatic species. The darkest shading represents high probability of chronic toxicity (>10 times the toxicity threshold); lighter shading represents moderate probability of chronic toxicity (1 to 10 times the toxicity threshold); and unshaded areas represent low probability of chronic toxicity (<toxicity threshold).
- Occurrence intervals are based on an overall predicted incident frequency of 0.0001190,000133 incident/mile*year, projected frequencies of each spill volume, and estimated stream widths.

Widths of higher flow streams are greater than widths of lower flow streams, with more distance where an incident might occur. This results in a greater predicted frequency for high flow streams and a corresponding lower occurrence interval.

The likelihood of a release into any single waterbody is low, with an occurrence interval of once every ~~2523~~2523,000 to ~~900840~~900840,000 years (**Tables 4-7 through 4-10**). If any release did occur, it is likely that the total release volume of a spill likely would be 3 barrels or less based on historical spill volumes.

While a release of crude oil into any given waterbody might cause immediate localized toxicity to aquatic biota, particularly in smaller streams and rivers, the frequency of such an event would be very low. Nevertheless, streams and rivers with aquatic biota represent the sensitive environmental resources that could be temporarily impacted by a crude oil release.

Wetlands/ Reservoirs/ Lakes

Although planning and routing efforts have reduced the overall number of wetlands and static waterbody environments crossed by the Project, wetlands and waterbodies with persistently saturated soils are present along and adjacent to the Project route. The effects of crude oil released into a wetland environment will depend not only upon the quantity of oil released, but also on the physical conditions of the wetland at the time of the release. Wetlands include a wide range of environmental conditions. Wetlands can consist of many acres of standing water dissected with ponds and channels, or they may simply be areas of saturated soil with no open water. A single wetland can even vary between these two extremes as seasonal precipitation varies. Wetland surfaces are generally low gradient with very slow unidirectional flow or no discernable flow. The presence of vegetation or narrow spits of dry land protruding into wetlands also may isolate parts of the wetland. Given these conditions, spilled materials may remain in restricted areas for longer periods than in river environments.

Crude oil released from a subsurface pipe within a wetland could reach the soil surface. If the water table reaches the surface, the release would manifest as floating crude oil. The general lack of surface flow within a wetland would restrict crude oil movement. Where surface water is present within a wetland, the spill would spread laterally across the water's surface and be readily visible during routine ROW surveillance. The depth of soil impacts likely would be minimal, due to shallow (or emergent) groundwater conditions. Conversely, groundwater impacts within the wetland are likely to be confined to the near-surface, enhancing the potential for biodegradation. If humans or other important resource exposures were to occur in proximity to the wetland, then regulatory drivers would mandate the scope of remedial actions, timeframe for remediation activities, and cleanup levels. However, response and remediation efforts in a wetland have the potential for appreciable adverse effects from construction/cleanup equipment. If no active remediation activities were undertaken, natural biodegradation and attenuation would ultimately allow a return to preexisting conditions in both soil and groundwater. This would likely require a timeframe on the order of tens of years. Keystone will utilize the most appropriate cleanup procedures as determined in coordination with the applicable federal and state agencies.

The chance of a spill occurring at any specific wetland along the pipeline is very low. Based on survey data and aerial interpretation, the Project will cross 5.3 miles of wetlands in Montana. Of the estimated maximum of one spill postulated to occur during a ~~3026~~3026-year period within Montana, there is a 1.9 percent probability that the spill would occur within wetland areas.

The predicted effects of a spill reaching standing water (e.g., reservoirs, lakes) would depend largely upon the volume of crude oil entering the waterbody and the volume of water within the waterbody.

Table 4-11 summarizes the amount of water necessary to dilute spill volumes below aquatic toxicity and drinking water thresholds. While this preliminary approach does not account for fate and transport mechanisms, mixing zones, environmental factors, and emergency response capabilities, it does provide an initial benchmark for identifying areas of potential concern.

Table 4-11 Amount of Water Required to Dilute Crude Oil Spills Below Threshold Values

Barrels of Crude Oil	Volume of Water Required to Dilute Crude Oil Below Threshold (acre-feet) ¹		
	Acute Toxicity Threshold (7.4 milligrams per liter [mg/L])	Chronic Toxicity Threshold (1.4 mg/L)	Drinking Water MCL (0.005 mg/L)
Diluted Bitumen			
3	0.3 0.07	1.5 0.39	413 108
50	4.6 1.3	24.3 6.9	6,890 1,933
1,000	92.0 26.1	486.2 138	136,136 38,668
10,000	919.8 261	4,862.0 1,381	1,361,358 386,678
Synthetic Crude			
3	0.04 0.015	0.2 0.077	55 21.6
50	0.6 0.26	3.0 1.4	841 387
1,000	11.4 5.2	60.1 27.6	16,826 7,734
10,000	113.7 52	600.9 276	168,258 77,336

¹ Thresholds based on aquatic toxicity and drinking water thresholds established for benzene. The estimated benzene content of the diluted bitumen is 0.15 percent by weight. The synthetic crude oil is estimated to have a benzene content of 0.032 percent by weight.

Based on a review of publicly available toxicity literature for wetland plant groups (i.e., algae, annual macrophytes, and perennial macrophytes), crude oil is toxic to aquatic plants but at higher concentrations than observed for fish and invertebrates. Therefore, spill concentrations that are less than toxic effect levels for fish and invertebrates (see Aquatic Organisms, above) also would not affect wetland plant species.

In summary, while a release of crude oil into wetland and static waterbodies has the potential to cause temporary environmental impacts, the frequency of such an event would be very low.

4.3 Risk to Populated and High Consequence Areas

Consequences of inadvertent releases from pipelines can vary greatly, depending on where the release occurs. Pipeline safety regulations use the concept of HCAs to identify specific locales and areas where a release could have the most significant adverse consequences. HCAs include populated areas, drinking water, and unusually sensitive ecologically resource areas (USAs) that could be damaged by a hazardous liquid pipeline release. **Table 4-12** identifies the types and lengths of HCAs crossed by the Project. Portions of the pipeline that could affect HCAs if a spill occurred (contributory pipeline segments [CPS]) are subject to higher levels of inspection, per 49 Code of Federal Regulations (CFR) Part 195. These data are compiled from a variety of data sources, including federal and state agencies (e.g., state drinking water agencies, the Environmental Protection Agency). The PHMSA acknowledges that spills within a sensitive area might not actually impact the sensitive resource and encourages operators to conduct detailed analysis, as needed. Keystone has conducted an evaluation of HCAs crossed or located downstream of the pipeline. Keystone has identified a total of 4.7 miles of pipeline in Montana (approximately 1.7 percent) that either crosses or has the potential to affect HCAs through downstream transport.

These CPS will be subject to higher levels of inspection, as required by 49 CFR Part 195. Furthermore, Keystone has subsequently evaluated the location of valves as a measure to reduce potential risk to HCAs. As a result of the HCA evaluation, Keystone moved some proposed valve locations and added valves in specific locations to protect HCAs in Montana.

Assuming that one spill occurred along the Project in a ~~30~~26-year period, it is estimated that there is a ~~1.6~~1.6 percent chance that the spill would occur within an HCA. Although the number of predicted spills in HCAs is very small, the potential impacts of these individual spills are expected to be greater than in other areas due to the environmental sensitivity within these areas. **Table 4-13** also shows the number of spills and their predicted sizes.

Table 4-12 Release and Spill Volume Occurrence Interval Associated with the Project

	Miles of Pipe ¹	Total Number of Predicted Spills Occurrence Interval	<3 barrels	3 to 50 barrels	50 to 1,000 barrels	1,000 to 10,000 barrels
Populated Areas	1.3	0.00017 (5,800 years) 15 (6,500 years)	0.00009 (11,600 years) 08 (12,900 years)	0.00005 (19,300 years) 05 (18,500 years)	0.00003 (38,600 years) 02 (64,600 years)	0.000008 (128,500 years) 007 (143,600 years)
Drinking Water Areas	0.9	0.00012 (8,400 years) 1 (9,300 years)	0.00006 (16,700 years) 05 (18,700 years)	0.00004 (27,800 years) 04 (26,700 years)	0.00002 (55,700 years) 01 (93,400 years)	0.000005 (185,600 years) 005 (207,500 years)
Ecologically Sensitive Areas	3.2	0.00043 (2,400 years) 4 (2,600 years)	0.00021 (4,700 years) 2 (5,300 years)	0.00013 (7,800 years) 1 (7,500 years)	0.00006 (15,700 years) 03 (26,300 years)	0.00002 (52,200 years) 02 (58,400 years)

¹ The amount of pipe that has the potential to affect an HCA in the unlikely event of a spill. Probability of a spill was based on the conservative incident frequency of ~~0.000119~~0.000133 incidents per mile per year. These areas overlap; the total length of pipeline that could affect HCAs in Montana is 4.7 miles.

4.3.1 Populated Areas

PHMSA defines populated area HCAs based on US Census data. While there are no populated area HCAs crossed by the Project in Montana (**Table 4-12**), Keystone has identified 1.3 miles of CPS where a crude oil spill from the pipeline could potentially be transported downstream to a populated HCA. CPS locations will be subject to higher levels of inspection, as required by 49 CFR Part 195, in order to reduce the chance of pipeline incident.

4.3.2 Drinking Water

PHMSA identifies certain surface water and groundwater resources as drinking water USAs (49 CFR Part 195.6 and 49 CFR 195.450). Surface water USAs include intakes for community water systems and non-transient non-community water systems that do not have an adequate alternative drinking water source. Groundwater USAs include the source water protection area for community water systems and non-transient non-community water systems that obtain their water supply from a Class I or Class IIA aquifer and do not have an adequate alternative drinking water source. If the source water protection area has not been established by the state, the wellhead protection area becomes the USA.

Surface water USAs identified for their potential as a drinking water resource have a 5-mile buffer placed around their intake location. The groundwater USAs have buffers that vary in size. Source water protection areas in Montana are designated by the state and are 0.5 mile in diameter.

In Montana, there are no drinking water HCAs crossed by the Project **(Table 4-12)**. Keystone has identified 0.9 mile of CPS where a crude oil spill from the pipeline could potentially be transported downstream to a populated HCA. CPS locations will be subject to higher levels of inspection, as per 49 CFR Part 195, in order to reduce the chance of pipeline incident.

4.3.3 Ecologically Sensitive Areas

Certain ecologically sensitive areas are classified as HCAs by PHMSA due to potential risks to ecologically sensitive resources. These areas focus on the characteristics of rarity, imperilment, or the potential for loss of large segments of an abundant population during periods of migratory concentration. These include:

- Critically imperiled and imperiled species and/or ecological communities;
- Threatened and endangered species (or multi-species assemblages where three or more different candidate resources co-occur);
- Migratory waterbird concentrations;
- Areas containing candidate species or ecological communities identified as excellent or good quality; and
- Areas containing aquatic or terrestrial candidate species and ecological communities that are limited in range.

An isolated segment (0.4 miles in length) of the Project in Montana crosses an ecologically sensitive HCA **(Table 4-12)**. Keystone has identified an additional 2.8 miles of CPS locations that have the potential to affect HCAs. All these areas will be subject to higher levels of inspection, as required by 49 CFR Part 195, in order to reduce the chance of pipeline incident.

4.3.4 Management of Risk Within HCAs

To protect particularly sensitive resources, portions of the pipeline that have the potential to affect an HCA would be subject to a higher level of inspection per USDOT regulations. Federal regulations require periodic assessment of the pipe condition and timely correction of identified anomalies within HCAs. Keystone will develop management and analysis processes that integrate available integrity-related data and information and assess the risks associated with segments that can affect HCAs.

Due to Homeland Security concerns, the precise risk for specific locations of HCAs is highly confidential. Keystone will provide a confidential evaluation of site-specific risk to HCAs for federal agencies' review. As required by federal regulations (Integrity Management Rule, 49 CFR Part 195), the site-specific evaluation of risk is an ongoing process and is regulated by the PHMSA.

Based on Keystone's preliminary assessment of HCAs, some valve locations were moved from their initial locations and additional valves have been added to provide supplemental protection of HCAs, where warranted. In addition, Keystone will develop and implement a risk-based integrity management program (IMP). The IMP will use state-of-practice technologies applied within a comprehensive risk-based methodology to assess and mitigate risk associated with all pipeline segments including HCAs.

5.0 Keystone's Pipeline Safety Program

Pipelines are one of the safest forms of crude oil transportation and provide a cost-effective and safe mode of transportation for oil on land. Overland transportation of oil by truck or rail produces higher risk of injury to the general public than the proposed pipeline (USDOT 2002). The Project will be designed, constructed, and maintained in a manner that meets or exceeds industry standards.

Historically, the most significant risk associated with operating a crude oil pipeline is the potential for third-party excavation damage. The pipeline will be built within an approved ROW and markers will be installed at all road, railway, and water crossings. The depth of cover required by federal regulations is 30 inches in most locations. In an effort to reduce excavation damage, Keystone has taken the proactive measure to increase the typical depth of cover to 4 feet (18 inches more cover than federal requirements). Keystone also will mitigate third-party excavation risk by implementing a comprehensive Integrated Public Awareness program focused on education and awareness in accordance with 49 CFR Part 195.440 and API RP1162. Further, Keystone's operating staff will complete regular visual inspections of the ROW (at least once every 3 weeks and a minimum of 26 times per year) as per 49 CFR Part 195.412 and monitor activity in the area to prevent unauthorized trespass or access.

Keystone will have a maintenance, inspection, and repair program that ensures the integrity of the pipeline. Keystone's annual Pipeline Maintenance Program (PMP) will be designed to maintain the safe operation of the pipeline. The PMP will include routine aerial patrol of the ROW, periodic inline inspections, and cathodic protection readings underpinned by a company-wide goal to ensure facilities are reliable and in service. Data collected in each year of the program will be fed back into the decision-making process for the development of the following year's program. In addition, the pipeline will be monitored 24 hours a day, 365 days a year from the oil control center using leak detection systems and supervisory control and data acquisition (SCADA). During operations, Keystone will have a Project Emergency Response Program in place to manage a variety of events.

6.0 Conclusion

In summary, this conservative analysis of the proposed Project shows that the predicted frequency of incidents is very low, the probability of a large spill occurring is very low, and, consequently, risk of environmental impacts is minimal. Compliance with regulations, application of Keystone's IMPs and Emergency Response Plan, as well as adherence to safety procedures will help to ensure long-term, environmentally sound, and safe operation of the pipeline.

8.0 Glossary

Accidental Release

An accidental release is an unplanned occurrence that results in a release of oil from a pipeline.

Acute exposure

Exposure to a chemical or situation for a short period of time.

Acute toxicity

The ability of a substance to cause severe biological harm or death soon after a single exposure or dose.

Adverse effect

Any effect that causes harm to the normal functioning of plants or animals due to exposure to a substance (i.e., a chemical contaminant).

Algae

Chiefly aquatic, eukaryotic one-celled or multicellular plants without true stems, roots and leaves that are typically autotrophic, photosynthetic, and contain chlorophyll. They are food for fish and small aquatic animals.

Aquifer

An underground layer of water-bearing permeable rock, or unconsolidated materials (gravel, sand, silt or clay) from which groundwater can be usefully extracted using a water well.

Barrel

A barrel is a standard measure of a volume of oil and is equal to 42 gallons.

Bioavailability

How easily a plant or animal can absorb a particular contaminant from the environment.

Biodegradation

Biodegradation is the breakdown of organic contaminants by microbial organisms into smaller compounds. The microbial organisms transform the contaminants through metabolic or enzymatic processes. Biodegradation processes vary greatly, but frequently the final product of the degradation is carbon dioxide or methane.

BPD

Abbreviation for barrels per day

Cathodic Protection System

A technique to provide corrosion protection to a metal surface by making the surface of the metal object the cathode of an electrochemical cell. In the pipeline industry that is done using impressed current. Impressed current cathodic protection (ICCP) systems use an anode connected to a DC power source (a cathodic protection rectifier).

Chronic toxicity

The capacity of a substance to cause long-term poisonous health effects in humans, animals, fish, or other organisms. Biological tests use sublethal effects, such as abnormal development, growth, and reproduction, rather than mortality, as endpoints.

Contaminant

Any physical, chemical, biological, or radiological substance found in air, water, soil or biological matter that has a harmful effect on plants or animals; harmful or hazardous matter introduced into the environment.

Ecosystem

The sum of all the living plants and animals, their interactions, and the physical components in a particular area.

Exposure

How a biological system (i.e., ecosystem), plant, or animal comes in contact with a chemical.

Event

An event is a significant occurrence or happening. As applicable to pipeline safety, an event could be an accident, abnormal condition, incident, equipment failure, human failure, or release.

Facility

Any structure, underground or above, used to transmit a product.

Habitat

The place where a population of plants or animals and its surroundings are located, including both living and non-living components.

High Consequence Area (HCA)

A high consequence area is a location that is specially defined in PHMSA pipeline safety regulations as an area where pipeline releases could have greater consequences to health and safety or the environment. For oil pipelines, HCAs include high population areas, other population areas, commercially navigable waterways, and areas unusually sensitive to environmental damage, including certain ecologically sensitive areas and drinking water resources. Regulations require a pipeline operator to take specific steps to ensure the integrity of a pipeline for which a release could affect an HCA and, thereby, provide protection of the HCA.

High Population Area

A high population area is an urbanized area, as defined and delineated by the US Census Bureau, which contains 50,000 or more people and has a population density of at least 1,000 people per square mile. High population areas are considered HCAs.

Incident

As used in pipeline safety regulations, an incident is an event occurring on a pipeline for which the operator must make a report to the Office of Pipeline Safety. There are specific reporting criteria that define an incident that include the volume of the material released, monetary property damage, injuries, and fatalities (Reference 49 CFR 191.3, 49CFR 195.50).

Incident Frequency

Incident frequency is the rate at which failures are observed or are predicted to occur, expressed as events per given timeframe.

Integrity Management Program

An IMP is a documented set of policies, processes, and procedures that are implemented to ensure the integrity of a pipeline. An oil pipeline operator's IMP must comply with the federal regulations (i.e., the Integrity Management Rule, 49 CFR 195).

Integrity Management Rule

The Integrity Management Rule specifies regulations to assess, evaluate, repair, and validate the integrity of hazardous liquid pipelines that, in the event of a leak or failure, could affect HCAs.

Invertebrates

Animals without backbones: e.g., insects, spiders, crayfish, worms, snails, mussels, clams, etc.

LC₅₀

A concentration expected to be lethal to 50 percent of a group of test organisms.

Leak

A leak is a small opening, crack, or hole in a pipeline allowing a release of oil.

Likelihood

Likelihood refers to the probability that something possible may occur. The likelihood may be expressed as a frequency (e.g., events per year), a probability of occurrence during a time interval (e.g., annual probability), or a conditional probability (e.g., probability of occurrence, given that a precursor event has occurred).

Maximum Contaminant Level (MCL)

The maximum level of a contaminant allowed in drinking water by federal or state law and is based on the avoidance of health effects and currently available water treatment methods.

National Pipeline Mapping System (NPMS)

The National Pipeline Mapping System is a GIS database that contains the locations and selected attributes of natural gas transmission lines, hazardous liquid trunklines, and liquefied natural gas (LNG) facilities operating in onshore and offshore territories of the United States.

Operator

An operator is a person who owns or operates pipeline facilities (Reference 49 CFR 195.2).

Polycyclic Aromatic Hydrocarbons (PAHs)

Group of organic chemicals.

Pipeline

Used broadly, pipeline includes all parts of those physical facilities through which gas, hazardous liquid, or carbon dioxide moves in transportation. Pipeline includes but is not limited to: line pipe, valves and other appurtenances attached to the pipe, pumping/compressor units and associated fabricated units, metering, regulating, and delivery stations, and holders and fabricated assemblies located therein, and breakout tanks.

Receptor

The species, population, community, habitat, etc. that may be exposed to contaminants.

Risk

Risk is a measure of both the likelihood that an adverse event could occur and the magnitude of the expected consequences should it occur.

Sediment

The material of the bottom of a body of water (i.e., pond, river, stream, etc.).

Stressor

Any factor that may harm plants or animals; includes chemical (e.g., metals or organic compounds), physical (e.g., extreme temperatures, fire, storms, flooding, and construction/development) and biological (e.g., disease, parasites, depredation, and competition).

Supervisory Control and Data Acquisition System (SCADA)

A SCADA is a pipeline control system designed to gather information such as pipeline pressures and flow rates from remote locations and regularly transmit this information to a central control facility where the data can be monitored and analyzed.

Throughput

The volume of oil through a pipeline during a specified time (e.g., barrels per day).

Toxicity Threshold

Numerical values that represent concentrations of contaminants in abiotic media (sediments, water, soil) or tissues of plants and animals above which those contaminants are expected to cause harm.

Unusually Sensitive Areas (USAs)

USAs refers to certain drinking water and ecological resource areas that are unusually sensitive to environmental damage from a hazardous liquid pipeline release, as defined in 49 CFR 195.6.

Zooplankton

Small, usually microscopic animals (such as protozoans) found in lakes and reservoirs.

Description:

50cfrROWapp.doc

Patricia--

Jerry Rodriguez, Medicine Lake NWR in MT, has asked me to contact you in order to answer your question below pertaining to Congressional notification. I have attached a copy of 50 CFR which talks specifically about ROW applications. Section 29.21-9 discusses ROW for gas/pipelines. Letter 'm' discusses Congressional notification and the time limitations for that part of the process. To briefly answer your questions, yes we would have to ask for Congressional notification. Another resource I have attached is the link to the Keystone Pipeline proposal and information we are working on that is going through the eastern part of the Dakotas. This may help you in some of your questions as well. I hope these two resources answer your questions.

(See attached file: 50cfrROWapp.doc)

www.fws.gov/mountain-prairie/keystonepipeline/

Now that we have been connected, I have a couple of questions for you on the Keystone XL project. First, have you been in touch with Tim Modde, our Denver Regional Office NEPA coordinator?

Also, are you preparing the EIS for all three alternative routes? I am also a Realty Specialist for Bowdoin NWR and Charles M. Russell NWR (CMR) in MT. The proposed pipeline is not crossing any of these refuge lands. However, I believe it may cross potential wetland easements in the Bowdoin district and the powerlines to the proposed route cross a small portion of primary jurisdiction of CMR. If you are not the EIS coordinator for these alternatives, do you know who is? We have some questions about the CMR portion and have been unable to find out who to contact with these questions. Do you know if the FWS is a cooperating agency for this project and EIS? If so, could you tell me who signed the documents (was it at the national level or Denver level), or maybe even send me a copy of the agreement?

Thanks, so much, Patti, for your help and guidance the last part of this email. It would be wonderful to start moving forward with this project on our end of things. I am hopeful to hear from you soon.

Issue: MFSA Visual Resources Contrast Rating Approach Concern Level: High___Moderate X Low___

Description:

Contrast Rating Approach:

I told NJ that I didn't think that a contrast rating "overlay" was workable, but suggested that I would do contrast ratings for KOPs at major road crossings using a summary table based on BLM VRM contrast rating procedures.

- o She agreed that this approach sounded good.
- o She has received the annotated photos & said they gave her a much better sense of the landscape we were dealing with in NE MT.

Issue: Reclamation Problem AreasConcern Level: High__Moderate_X_Low

:

Description:

Regarding reclamation potential, I noted that the reclamation difficulty spreadsheet I'd received was broken down into segments as small as .04 mi. (~200 ft.), or less, & I thought it was unworkable to address visual effects on such a fine scale.

- o NJ agreed; she said she was most interested in large areas with high visual sensitivity, e.g. rocky areas on terrain raised up in front of a major highway crossing.

Issue: Missouri River CrossingConcern Level: High__Moderate_X_Low__.**Description:**

She asked about how we would be going through the bluffs at the Missouri River crossing?

- o I said I thought it would be directionally drilled, but would check.

Follow-up Required / Requested

Check on directional drilling end points for Missouri River crossing.

Description:

Max Murphy contacted me after I sent a set of transmission line alternative maps to Jim Greil who is the Montana Department of Transportation Aeronautics Bureau Chief. These maps contained the location of two airports within the project vicinity (Circle Town Airport and Big Sky Field Airport). Here is what he answered back with:

Kyle

Just to put what I said in writing, your company needs to be concerned that you don't penetrate the 34:1 slope off of runway 12, which begins 200' level from the runway end, and extends over a section of the railroad tracks. Your option next to the rail tracks, has the possibility of penetration of the 34:1 runway slope.

Also the idea of installing balls on the power line will be very helpful for liability, the same is true at Big Sky Field where the power line comes nearest to the end of runway. In Circle airport it would be wise to consider putting sight balls of the end of turf runway 21 also. Along those power lines make sure to file 7460 forms with the FAA for the air obstructions that your company has plans to construct.

I hope the planning and construction goes well, thanks.

Max

Tribal Historic Preservation Officer John Murray
Blackfeet Nation
PO Box 2809
Quarter 108, E. Gov. Square
Browning, MT 59417

RE: TransCanada - Keystone XL Pipeline

Dear Mr. Murray,

TransCanada, a leader in the responsible development and reliable operation of North American energy infrastructure, is proposing to construct a 36-inch-diameter crude oil pipeline, the Keystone XL Pipeline Project, from Hardisty, Alberta, Canada, to the Port Arthur and east Houston areas of Texas in the United States (U.S.). Phase 2 of the Project consists of approximately 851 miles of the Mainline pipeline to be located between the U.S./Canadian border and Steele City, Nebraska. Phase 1 of the Project consists of approximately 476 miles of the Mainline pipeline proposed between Cushing, Oklahoma and Nederland, Texas. The Houston Lateral pipeline also is proposed to extend the approximately 50 miles from Nederland to the Port of Houston. A brochure providing an overview of the project is enclosed.

As planned, the pipeline will be constructed within an area generally 110 feet wide, consisting of both a temporary 60-foot-wide construction right-of-way (ROW) and a 50-foot-wide permanent ROW or easement. The enclosed maps are generalized illustrations of the proposed routes. The Phase 2 portions of the Mainline will be constructed in a new ROW that is not co-located with any existing utilities. The majority of Phase 1 of the Project and all of the Houston Lateral are co-located with existing pipelines and/or electrical utilities. Phase 1 is expected to be constructed in 2010, and Phase 2 in 2011.

TransCanada has retained ENSR to complete the field studies and permitting for the Project. To support these efforts, ENSR has retained subcontractors to complete the necessary cultural resource investigations. The lead federal agency for this project is the Bureau of Land Management (BLM), which will consult with the State Historic Preservation Offices (SHPOs), Tribal Historic Preservations Offices (THPOs), and federally recognized tribes with historic ties to the lands to be crossed by the Mainline and Houston Lateral pipelines. TransCanada has also requested that we start discussions with interested Native American tribal organizations to facilitate project review and coordination.

BLM will engage tribes when they have begun their analysis of the project, likely later this summer or early fall. In the interim, we are required to start our field survey program and would like to engage you to discuss tribal concerns related to field surveys. Engaging at this time will allow you to contribute to the identification, evaluation, and protection or treatment of historic properties that may be of particular interest or concern to your tribe, especially those of religious or cultural significance.

If you would prefer to deal directly with the BLM through government-to-government consultation, please let us know, and we can certainly provide you with names, addresses, and phone numbers of the appropriate people to contact.

If you would like to start early discussions with us on this project, then please let us know so that we can send you relevant Project documents. These include more detailed maps, file research review results, and survey methodologies. We are about to begin the field inventory in the Area of Potential Effects of the proposed Mainline. As such, we have developed Survey Protocols in consultation with the SHPOs and we would like to share these documents with interested tribes.

May 29, 2008
Page 2

If you have any interest in this Project and in the historic properties that may be affected, or in participating in the field surveys, please contact us within 30 days. Our field investigations will take place this summer. You may contact us at any time. A prompt response will allow us to convey your interests and concerns to the BLM and SHPOs early in the planning and permitting process.

We can be reached at any time at the following address and phone numbers, and we look forward to hearing from you soon.

Sincerely,

Scott Patti

Keystone XL Project – Montana Major Facility Siting Act Application

Table N-4 Access Road Additional Information Overview

Generalized Rule Content	Miles Crossed			Location in Document	AR Comment
	Route A	Route A1A	Route B		
c) Poor or seasonally restricted areas	NA	NA	NA	Attachment P, page 3, Response to SIR-1, Section	The access roads identified will be used for construction only. Construction is not anticipated during periods of limited access; therefore poor access should not be of concern during those periods. Roads will be reclaimed and will not be used during operation of the pipeline.
d) Compatibility or interference with transmission, transportation or communication facilities	NA	NA	NA		Temporary construction and use of access roads is anticipated to cause no impacts to transmission, transportation, or communication facilities.
e) Discussion and supporting documentation of problems or concerns associated with crossing highways or encroachment on highway ROWs through consultation with the Montana Department of Transportation (MDT).	NA	NA	NA	Attachment A, Mapbook 1 Section 4.3.11.2	Access roads do not cross any major thoroughfares. Refer to text for MDT consultation.
f) Floodplains	1.8	3.0	0	Attachment A, Mapbook 3	Because access roads will be temporary and will not be used in inclement weather, no adverse impacts to floodplains resulting from use are anticipated.
10. Visual resource and viewer information					See below
a) Scenic quality overlay	See comment			Attachment P, page P-123	Scenic quality rating: C (see visual quality overlay)

Keystone XL Project – Montana Major Facility Siting Act Application

Table N-4 Access Road Additional Information Overview

Generalized Rule Content	Miles Crossed			Location in Document	AR Comment
	Route A	Route A1A	Route B		
b) Visual contrast overlay	See comment			Attachment P, page P-123	Visual contrast rating: Visual contrast would be “weak” to “none” at 5 years, after reclamation. (Pipeline visual effects were assessed for KOPs; no overlay was prepared. See visual contrast table for nearest contrast rating).
c) Tabulation of classes of scenic quality	See comment			Attachment P, page P-123	See visual quality table
d) Explanation of any difference with FS visual inventory maps	See comment			-	Forest Service land is not located on any or near any access roads, hence No FS visual inventory.

Keystone XL Project – Montana Major Facility Siting Act Application

Table N-4 Access Road Additional Information Overview

Generalized Rule Content	Miles Crossed			Location in Document	AR Comment
	Route A	Route A1A	Route B		
e) Identification of key observation points	See comment			-	The access road originates at a very low traffic volume county road. The nearest residence, a farmstead, is approximately 0.6 mile SSW of the road intersection. Neither would be considered a KOP.
f) Viewer characteristics	See comment			-	Local resident ranchers and farmers; sensitivity expected to be fairly low.
g) Photographs from observation points	See comment			Attachment P, page P-64	See photo B 269.0-160-CR247 for comparable landscape character, although the location of the access road would be flat and nearly level.
h) Viewsheds for key observation points	See comment			-	Areas as defined in 3.7(10)h are not crossed by access road, therefore viewsheds for key observation points are not required.
11. Assessment of visual resource impacts	See comment			-	Visual resource impacts would be minimal and temporary. The road would be reclaimed after construction.
12. Description of existing biological resources and an assessment of impacts to these resources for each alternative and access roads...	NA	NA	NA

Electrical Transmission Lines

Electrical service requirements for the Project include utilizing existing service lines and the construction of electrical transmission and distribution transmission lines to pump stations and delivery facilities. Because local electrical power providers, not Keystone, will be constructing and operating the electrical transmission lines, the electrical transmission companies will be responsible for obtaining any necessary approvals or authorizations from federal, state, and local governments. While the permitting process for the electrical facilities is an independent process from the pipeline ROW approval process, the construction and operation of these transmission lines are considered connected actions under NEPA and MEPA and, therefore, are evaluated within this application for the Project. Keystone has requested a clarification from Montana DEQ (MDEQ) with regard to the treatment of the transmission lines, but for the current application filing, Keystone is evaluating the preliminary transmission lines along the preferred route and alternative routes as associated facilities. Associated facilities are described in Circular MFSA-2, Section 3.7(12) and Section 3.8 (1)(v). These sections were used to evaluate potential impacts to resources due to construction and maintenance activities.

Electrical Transmission Line Requirements

New electrical transmission lines (i.e., transmission lines with voltage of 69 kilovolts [kV] or greater) will be constructed to service pump stations along the Project route in Montana. Other electric transmission requirements (e.g., at valve sites) will be supplied by distribution service drops from adjacent distribution transmission lines (i.e., transmission lines with voltage below 69 kV). Each of these distribution service drops will require the installation of approximately one or two poles and a transformer. The length of these distribution service drops typically will be less than 200 feet. Permitting and construction of these transmission lines would be performed by the local power providers. Power providers would restore the work area as required upon completion of the new service drops in accordance with local standards and applicable permits.

Table O-1 provides preliminary details for the new electrical transmission lines associated with the Project pump stations. In conjunction with local power providers, Keystone has identified proposed routing for each transmission line along the preferred [pipeline](#) route (Route B). Additionally, Keystone has identified preliminary routes for transmission lines that would service the pump station locations along the alternative pipeline routes (Route A and A1A). Where feasible, the entire length of each of these proposed or preliminary transmission line routes (Routes) has been placed along existing county roads, section lines, or field edges to minimize interference with adjacent agricultural lands. The Routes that link existing transmission lines to each pump station along the preferred ~~route~~ and alternative [pipeline](#) ~~R~~ routes are illustrated in **Attachment A, Transmission Line, Figure 1**.

Furthermore, criteria from Circular MFSA-2, Sections 3.2, 3.4, and 3.7 were incorporated into [power line](#) route analysis that would either avoid, or allow means for mitigation of, adverse impacts to resources outlined in Section 3.7(12) and Section 3.8(1)(v). Avoidance areas and land ownership including national wildlife refuges, state wildlife management areas are described in **Attachment A, Transmission Line, Figure 1**.

Electrical Transmission Line Construction

The construction phase for each electrical transmission line will consist of ROW acquisition, ROW clearing, construction, and site restoration and cleanup. The following is a brief summary of the typical steps associated with transmission line construction. Actual transmission line construction procedures will be developed by each transmission provider to address site-specific conditions.

- ROW easements. The electric utilities will obtain any necessary easements.
- ROW clearing. Limited clearing will be required along existing roads in rangelands, grasslands, and croplands. Some trees may require removal to provide adequate clearance between the conductors and underlying vegetation. Trimming to avoid tree removal may be employed in some locations.
- Transmission line construction. The structures will be delivered on flatbed trucks. A mobile crane or picker truck may be needed to install the poles. Holes will be excavated for structure placement, typically with radial arm diggers. The wooden or steel poles will be directly embedded into the ground and anchors may be required at angles and dead ends. Pulling or reeling areas will be needed for installation of the conductor wires. Conductors (wires) will be attached to the structure using porcelain or fiberglass insulators.
- Restoration. After the transmission line structures are in place and the conductors are strung between the structures, the disturbed areas will be restored. The soil in the disturbed areas will be reshaped

Keystone XL Project – Draft Montana Major Facility Siting Act Application

and contoured to its original condition. Reseeding will follow landowner requirements. All litter and other remaining materials will be removed from the construction areas and properly disposed.

Affected Environment and Environmental Consequences

This section addresses the resources affected by the construction, operation, and maintenance of the proposed electrical transmission lines associated with the Project. Impacts associated with the electrical distribution line service drops are expected to be minimal and comparable to those associated with supplying electricity to the average home or farm, and are not further addressed. The following analysis assumes that existing access roads will be utilized for construction and maintenance of the Routes. It is also assumed that further review of potential construction and/or improvement of access roads will be conducted by the local power providers.

The proposed and alternative transmission line Routes were evaluated for potential environmental impacts through aerial photo interpretation. Further environmental review of the Routes will be carried out by the local power providers as required by their respective transmission line permitting processes.

Land Ownership

The linear mileage crossed by the [power line Routes](#) is categorized by surface ownership in **Table O-2**. Land ownership on all of the Routes is primarily private. Routes on Alternatives A and A1A cross Tribal-owned lands, while Routes associated with Alternative B do not cross any Tribal-owned lands. All Routes cross state and federal lands. Land ownership along the Routes is shown in **Attachment A, Transmission Line, Figure 1**.

¹ Discrepancies in total mileage are due to rounding.

The Tribal land ownership type includes Bureau of Indian Affairs Trust Lands, Turtle Mountain Allotted Lands, as well as private lands on the Fort Peck Indian Reservation. Federal lands are predominantly BLM lands in both the Malta and Miles City Districts, but also include a short crossing of US Fish and Wildlife Service land on Route A1A and a crossing of US Department of Defense/Army Corps of Engineers property on Route B. State-owned land is almost exclusively Montana State Trust Lands.

Land Use

Land use associated with the ~~power line R~~ routes would be similar in character to those associated with the Project. The following overview of land use types within the proposed Routes represents information gathered from publicly available literature, federal, state, and local agencies, review of current and aerial photography. The information provides a baseline inventory of land usage occurring within the Routes. Land use is classified as the following:

- Developed: lands used for residential areas as well as industrial and commercial areas. Specifically, these areas contain all, but are not limited to houses, structures, roads, railroads, windbreaks, and cleared ROW;
- Agriculture/cropland: land suitable for or used for the cultivation of crops;
- Grassland/rangeland: land that is occupied by native herbaceous or shrubby vegetation which is grazed by domestic or wild herbivores. Grasslands can be native or improved land;
- Forest land: land consisting of wooded upland forests. This land is dominated by trees and shrubs and includes areas planted with trees for the pulp and/or paper industry;
- Water: rivers, streams, creeks, ponds, lakes, etc.; and
- Wetlands: low-lying areas of land that are saturated with moisture, especially when regarded as the natural habitat of wildlife. These lands include emergent wetlands, scrub/shrub wetlands, and forested wetlands.

Note: Discrepancies in totals are due to rounding.

The GIS Land Use layer for the three routes was digitized from 2006 aerial photos. The layer was subsequently compared and cropland types further attributed based on MDR agricultural land reappraisal layer. MDR layer is in development and no metadata were available for the dataset from the state.

Keystone XL Project – Draft Montana Major Facility Siting Act Application

Land use types crossed by the [power line](#) Routes are detailed in **Table O-3** in miles. The types of land use are categorized by agricultural land, grassland/rangeland, developed, forest land, wetland/riparian, and waterbody. Specific information on the types of agricultural lands also is included in the table. On Routes A, A1A, and B, the predominant land use type crossed [by power lines](#) is grassland/rangeland with cropland as the second most common type.

Impacts on land uses within the [power line](#) Routes could result from various project-related construction activities including: establishment of construction yards and staging areas; improving access roads; clearing and excavating tower sites and installing towers; removal of obstructions (e.g., vegetation and trees) along Routes; and installing conductors. Long-term impacts would be similar to those described for the Project and include:

- Temporary loss of agricultural productivity during the construction period;
- Visual impacts associated with the construction ROW, which include removal of existing vegetation, exposure of bare soils, and earthwork and grading scars;
- Visual impacts associated with transmission structure contrast and impacts on “natural” landscapes, or scenic quality impacts;
- Increased noise and dust to nearby residential and commercial areas from transmission line construction activities;
- No trees in ROW; and
- No other structures in ROW.

Vegetation

Vegetation communities crossed by the potential transmission line Routes would be similar to those described for the Project and are summarized in **Table O-4**. Because of the nature of transmission lines, minimal impacts to vegetation communities would be expected, with the exception of wooded areas, where trees and shrubs would be trimmed or cleared. Vegetative types were identified and delineated based on review of literature, internet database resources, aerial photography, and general observations made during field reconnaissance activities. The Routes traverse four vegetation types in the State of Montana. Vegetation types include agriculture, grasslands/rangeland, palustrine emergent/scrub-shrub/forested wetlands, and upland forest.

Transmission line construction would involve both the temporary and permanent alteration of vegetation during ROW preparation and excavation, high traffic activity, and the clearing of shrubs and trees. Vegetation recovery rates are estimated to be 1 to 5 years for herbaceous components, 5 to 15 years for low shrubs, and trees would not be allowed to return. After construction, reclamation of affected lands would be performed by the local power providers in accordance with local standards and associated permits.

Terrestrial and Aquatic Wildlife

Terrestrial and aquatic wildlife potentially impacted by the transmission line Routes would be similar to those described for the Project and are summarized in **Attachment H** (Special Status Species). **Attachment A, Confidential Transmission Line, Figure 1, to be filed with MDEQ**, details the location of sensitive species affected by the Routes including sage grouse leks and other sensitive species. **Attachment A, Transmission Line, Figure 2**, describes the big-game, fisheries, and avian resources potentially affected by the proposed Routes.

During construction, impacts to terrestrial and aquatic wildlife resources would be similar to those for the Project. The primary potential adverse impacts include direct mortality, habitat loss and fragmentation, disturbance and displacement of individual animals, interference with behavioral activities, and increased public access. Many impacts to habitat associated with sensitive species can be avoided during construction and operation by spanning these habitats therefore, relatively few permanent disturbances to terrestrial or aquatic wildlife would occur.

Transmission line construction could also include the improvement of access roads that may increase access to remote habitat and, therefore, increase hunting and fishing pressures on public properties. As shown in **Table O-2**, the Routes would cross approximately ~~70.3~~60 miles of public lands on Alternative B, ~~51.3~~56.5 miles on Alternative A, and ~~56.6~~61.7 miles on Alternative A1A. These public lands allow access to hunting and fishing. In addition, these associated facilities may provide additional access to the Missouri River, a Class II fishery.

Keystone XL Project – Draft Montana Major Facility Siting Act Application

Additionally, impacts to avian wildlife would occur related to permanent standing structures and associated facilities. The [power line](#) Routes cross rivers and riparian areas that are likely to attract [migratory birds including raptors, waterfowl, and whooping cranes](#). ~~raptors and migratory birds~~. The new transmission line segments will incrementally increase the collision potential for migrating and foraging bird species (e.g., raptors and migratory birds [APLIC 1994]). However, collision potential typically is dependent on variables such as the line location in relation to high use habitat areas (e.g., nesting, foraging, and roosting), line orientation to flight patterns and movement corridors, species composition, visibility, and line design. In addition, distribution lines that are less than 69 kV but greater than 1 kV could pose an electrocution hazard for raptor species attempting to perch on the structure. Configurations less than 1 kV or greater than 69 kV typically do not present an electrocution potential, based on conductor placement and orientation (APLIC 1996).

Spanning wetlands and waterbodies has the potential to increase impacts to [migratory birds including raptors, waterfowl, and whooping cranes](#). ~~raptors and migratory birds~~ that likely utilize these habitat locations. [Transmission lines associated with PS 12 on Route A1A crosses a diversion canal that supplies, and is included within, Medicine Lake NWR, an area important to waterfowl as described for the project in Section 4.3.4.3.](#) Other prime habitat locations occur in vegetated cover types grassland/rangeland and upland forest.

Potential collision and electrocution impacts to bird species from the Project could be reduced further if electrical service providers agree to implement the following mitigation measures.

- Incorporation of standard, safe designs, as outlined in Suggested Practice for Raptor Protection on Transmission Lines (APLIC 1996), into the design of electrical distribution lines in areas of identified avian concern to prevent electrocution of raptor species attempting to perch on the transmission poles and lines. These measures include, but are not limited to, a 60-inch separation between conductors and/or grounded hardware and recommended use of insulating materials and other applicable measures depending on line configuration (APLIC 1996).
- Incorporation of standard raptor-proofing designs, as outlined in Mitigating Bird Collision with Transmission Lines (APLIC 1994), into the design of the electrical distribution lines to prevent collision to foraging and migrating raptors within the project area, as applicable.

In addition to electrocution and collision impacts, transmission lines may have impacts to grouse species occurring along the route. According to the final management plan and conservation strategies for sage grouse in Montana (MSGWG 2005), “Transmission lines provide additional hunting perches for raptors in otherwise treeless areas. Transmission lines most likely impact grouse near leks, in brood-rearing habitat, and in wintering areas that also support large numbers of wintering raptors.”

Geology

Geologic resources found along the [power line](#) Routes would be similar in character to those associated with the Project. Generally, the geology consists of gently sloping sedimentary rocks of late Cretaceous to early Tertiary age. Stream erosion has formed dendritic drainage patterns producing moderate to steeply incised valleys. Extensive areas of glacial outwash and Quaternary fluvial deposits are exposed throughout each of the alternative Routes.

Potential issues associated with geology would be due to construction of the transmission lines; no additional impacts would be expected during operation. Issues could include potential hazards associated with seismic activities and landslides. Other hazards may result from construction on Cretaceous shales that contain bentonite beds. The high swelling hazard may cause slope instability during periods of precipitation.

Additionally, impacts would occur due to the upgrading of existing roads. Shales of the Bearpaw and Claggett formations are known to be susceptible to mass wasting and slope failure. The high swelling and high plasticity characteristics of these shales, coupled with their high slaking potential, tend to produce slope failure in

Keystone XL Project – Draft Montana Major Facility Siting Act Application

moderate to steep terrains. Areas of potential slope failure are shown in **Attachment A, Transmission Line, Figure 3**.

Water Resources

Wetlands and waterbodies crossed by the [power line](#) Routes are summarized in **Table O-5**. Wetlands within the Routes were classified into four categories: palustrine emergent wetlands (PEM); palustrine scrub-shrub wetlands (PSS); palustrine forested wetlands (PFO) and riverine/open water. Riverine/open water areas include any ephemeral, intermittent, or perennial stream as well as any ponds, lakes, reservoirs, or stock ponds.

Potential impacts to water resources and wetlands could result from accelerated erosion and sedimentation from the construction and maintenance activities on or adjacent to streams or wetlands. Other potential impacts include water quality degradation, and decreased wetland size, function, or value. In areas where potential impacts to water resources and wetlands are possible, mitigation measures would be expected to be effective in reducing or eliminating potential impacts.

Transmission line construction requires one utility location to be placed approximately 200 feet from the next utility location, therefore avoiding surface features such as streams and wetlands is possible by spanning the feature between two support poles. Therefore, the utility pole locations will be selected to minimize impacts to wetlands. Once transmission lines were in place, impacts would be minimal.

Mileages reflect national vegetation cover (USDA NRCS 2008).

Cumulative Impacts

Cumulative impacts are defined in the CEQ regulations 40 CFR 1508.7 as “...the impact on the environment that results from the incremental impact of the action when added to other past, present, and reasonably foreseeable actions regardless of what agency... or person undertakes such other actions.” These actions include current and projected area development (e.g., oil and gas); management activities and authorizations on public lands (e.g., rangeland conversion); land use trends; and applicable industrial/infrastructure components (e.g., utility corridors).

The construction of the electrical transmission and distribution transmission lines necessary for the Project will occur during the same timeframe and in the same general area as the Project. Construction activities will be of short duration in any single location. Most transmission lines will be co-located with other ROWs (i.e., roadways, pipeline corridors, and existing transmission lines) or located along field edges or section lines to reduce the overall amount of habitat fragmentation and interference with agricultural operations. The amount of land associated with the transmission line ROWs represents a small fraction of available native vegetation in the region. As a consequence, these transmission lines do not represent a substantial cumulative disturbance to the environment.

Other than the Keystone Pipeline Project, no foreseeable construction projects that overlap in space and time with the transmission lines were identified.

Power Lines Less than 10 Miles Long

Based on discussions with MDEQ power lines less than 10 miles long will be considered associated facilities for the purposes of this application. The following tables provide information on the alternative power line routes that meet this criterion.

The previous sections of this Attachment discuss a preferred power line Route for pump stations on all three pipeline route alternatives (A, A1A, & B) in Montana, regardless of length. This section provides information on three alternative power line Routes for the four pump stations with less than 10 miles of power line: PS 12 on Route A; PS 13 on Route A1A; and PS 12 and PS 14 on Route B.

Table O-6 provides data and information to address Circular MFSA-2 requirements in 3.2 and 3.4. Table O-7 provides data and information to address requirements in 3.7.

i). areas where the presence of the facility would be incompatible with published visual management plans or regulations designed to protect view sheds adopted by federal, state, or local governments.									The power lines are proposed primarily for VRM Class III and IV areas. They would be single-pole structures with 69kV or 115kV capacity conductors. They would be located in rural areas with grassland and agricultural uses. The visual contrast is judged to be moderate to weak for structural modifications, which would readily comply with VRM objectives for Class III and Class IV areas. All 3 alternatives for the proposed power line to serve Route A - PS 12 would cross into a VRM Class II area for approximately 0.4 to 0.8 mile. This Class II area exists primarily as a corridor along highway U.S. 2. The proposed power line would tie into an existing major transmission line (see photos A 172.7-340 - US2 and A 172.7-360 - US2). The 3 alternatives for this line would all be behind the existing transmission line, as seen from U.S. 2. Consequently, the introduced visual contrast would be similar to existing structures and is deemed to be weak, which would meet the VRM objective for a Class II area.
i. <u>Class II</u>	<u>0.4</u>	<u>0.5</u>	<u>0.8</u>		<u>0</u>	<u>0</u>	<u>0</u>		VRM Class Objective: To retain the existing character of the landscape. The level of change to the characteristic landscape should be low. (Miles crossed)

Power Line Analysis	Route A – PS 12			Route A1A – PS 13			Comments
	<u>Preferred</u>	<u>Alt 1</u>	<u>Alt 2</u>	<u>Preferred</u>	<u>Alt 1</u>	<u>Alt 2</u>	
10. Visual resource and viewer information							
a) Scenic quality overlay	See Below			See Below			An overlay was prepared for the pipeline ROWs (<u>Attachment P. Scenic quality overlay</u>); see item 10.c. below for a tabulation of scenic quality for areas outside the pipeline ROWs.
b) Visual contrast overlay	Route A - PS 12: Visual contrast for all Alts. would be moderate to weak for linear structures, with contrast for the preferred alt. slightly greater than for the other 2 alts. because of proximity to MT 16; VRM objectives for Class III & IV areas would be achieved. Contrast in the VRM Class II area to the south would be weak because the P-line would be behind the existing E-W T-line from the U.S. 2 motorists' perspective; the Class II VRM objectives would be met in this area as well.			Route A1A - PS 13: Visual contrast for all Alts. would be moderate to weak for linear structures; VRM class objectives would be met for Class IV, which encompasses the entire study area.			
c) Tabulation of classes of scenic quality	B=0.0; C=6.0	B=0.0; C=7.6	B=0.0; C=7.3	B=0.0; C=5.8	B=0.0; C=6.9	B=0.0; C=6.3	
d) Explanation of any difference with FS visual inventory maps	See Comment			See Comment			Forest Service land is not located on any or near any power line, hence no FS visual inventory.
e) Identification of key observation points	4 homes plus the NE edge of Culbertson town.	11 homes	12 homes plus the N edge of Culbertson town.	4 homes	6 homes	2 homes	Number of residences within 0.75 mi. is itemized to the left. Route A - PS 12: Preferred Alt. parallels MT 16 within 0.75 mi. for its entire length; Alt. 1 is within 0.75 mi. of MT 16 for approximately 3 miles; Alt. 2

Table 0-7 Power Line Additional Information Overview – Routes A and A1A

<u>Power Line Analysis</u>	<u>Route A – PS 12</u>			<u>Route A1A – PS 13</u>			<u>Comments</u>
	<u>Preferred</u>	<u>Alt 1</u>	<u>Alt 2</u>	<u>Preferred</u>	<u>Alt 1</u>	<u>Alt 2</u>	
							is within 0.75 mi. for approximately 2 miles; the southern tips of all 3 alternatives are within 0.75 mi. of U.S. 2. Route A1A - PS 13: There are no major roads or highways within 0.75 mi. of any of the 3 alternatives.
f) <u>Viewer characteristics</u>	Route A - PS 12: Viewers would include motorists on MT 16 and, to a lesser degree, U.S. 2; small town residents; and farmers/ranchers.			Route A1A - PS 13: Ranchers/farmers and oil & gas workers.			
g) <u>Photographs from observation points</u>	Route A - PS 12: See photos for M.P. 156.6, in particular A 156.6-110 - MT16 illustrates the site of Pump Station 13.			Route A1A - P.S. 13: Representative photos not available.			
h) <u>Viewsheds for key observation points</u>	See Comment			See Comment			Areas as defined in 3.7(10)h are not crossed by power line alternatives, therefore viewsheds for key observation points are not required.
11. <u>Assessment of visual resource impacts</u>	Route A - PS 12: All 3 alternatives would meet the VRM objectives for VRM Class II, III and IV areas; Alt. 1 has the least residential exposure; Alt. 2 has the least highway exposure.			Route A1A - PS 13: All 3 alternatives would readily meet the applicable VRM Class IV objectives.			
12. <u>Description of existing biological resources and an assessment of impacts to these resources for each alternative...</u>	See Comment			See Comment			Existing biological resources potentially impacted by the power line routes are generally discussed in the vegetation, terrestrial and aquatic wildlife, and water resources section of this Attachment.

Power Line Analysis	Preferred	Alt 1	Alt 2	Preferred	Alt 1	Alt 2	Comments
xvi. Major elk summer security areas	0	0	0	0	0	0	No major elk habitat is located along any power line.
xvii. Mountain goat and big horn sheep seasonal habitat	0	0	0	0	0	0	There is no mountain goat or big horn sheep habitat crossed by any power line.
xviii. Sage and sharp-tailed grouse leks and winter distribution	5.3	2.6	6.3	0	0	0	Lek areas include the actual lek site plus a four mile buffer for greater sage grouse and a two mile buffer for sharp-tailed grouse. Route A - PS 12 crosses approximately 2.6 to 6.3 miles of sharp-tailed lek areas. This analysis includes breeding areas only. Sage-grouse winter habitat is not available from MFWP. (Miles crossed)
Sage Grouse General Distribution	0	0	0	0	0	0	Not crossed; no impact
Sage Grouse Lek Area	0	0	0	0	0	0	Not crossed; no impact
Sage Grouse Leks within 4 Miles	0	0	0	0	0	0	None
Sharp-Tail Grouse General Distribution	2.0	4.1	2.5	5.8	6.9	6.3	All power line routes cross sharp-tailed grouse general distribution. According to the MFWP (personal communication, 5/28/2008), the sharp-tailed grouse is not listed as a species of concern, but they are lekking birds that have important breeding lek locations that need protection.

Table 0-7 Power Line Additional Information Overview – Routes A and A1A

	Route A – PS 12			Route A1A – PS 13			
Power Line Analysis	Preferred	Alt 1	Alt 2	Preferred	Alt 1	Alt 2	Comments
Sharp-tail Grouse Lek Area	5.3	2.6	6.3	0	0	0	Route A - PS 12 crosses within approximately 2.6 to 6.3 miles of sharp-tailed lek areas. This includes the actual lek site plus a two mile buffer for nesting activities. The BLM has a no surface occupancy stipulations within 1/4 mile of sharp-tail leks. MFWP recommends no surface use or disturbance within two miles of a lek from March 1 - June 15. Because the sharp-tailed grouse in not listed as a species of concern, MFWP would recommend that any disturbance to lek sites be done outside the breeding time (mid March - mid May).
Sharp-tail Grouse Leks within 4 Miles	4	1	6	0	0	0	Route A - PS 12 preferred route is within 2 miles of 4 historic sharp-tailed grouse lek sites. Alternate 1 is within 2 miles of 1 historic sharp-tailed grouse lek site. Alternative 2 is within 2 miles of 6 historic sharp-tailed grouse lek sites. (Number within 4 miles)
xix. High waterfowl population densities	0	0	0	0	0	0	Not crossed; no impact

	<u>Preferred</u>	<u>Alt 1</u>	<u>Alt 2</u>	<u>Preferred</u>	<u>Alt 1</u>	<u>Alt 2</u>	
c) A general assessment of impacts from hunting and fishing pressure if increased access to secure habitats would likely occur in the general vicinity of each alternative line location because new access roads would be constructed outside the impact zone	See Comment			See Comment			Currently, public lands are experiencing an increase in hunting. The construction of the power lines would not affect current hunting and fishing status. Hunting and fishing pressures on private lands would be site-specific and depend on whether the landowners allowed these activities on their property. A permanent access road on private lands that allowed hunting would increase hunting and/or fishing pressures in that area.
d) A description of the method used to evaluate impacts to wildlife, fisheries, and vegetation.	See Comment			See Comment			Refer to text in Chapter 4, Section 4.3.4.6
e) For impacts described in (b) and (c), a description of mitigating measures that could be implemented to reduce significant impacts and the cost of such measures.	See Comment			See Comment			Mitigation measures that agencies will require for the Project have not been defined. This will be addressed by the third-party power providers.

Clarifications and Responses to Supplemental Information Requests

September 2009 Filing

Keystone XL Project – Montana Major Facility Siting Act Application

|

Response to SIR-1, Section 17.20.1511(7)(b and c)

DEQ Request:

b) Estimates of trench width

Provide the width that the burial depth would be carried laterally to account for lateral stream channel migration.

2/23/09 – DEQ Incomplete. Provide the width that the burial depth would be carried laterally to account for lateral stream channel migration. This information is needed for analyses of impacts.

c) Estimates of scour depth

Keystone Response:

Keystone will comply with applicable requirements for trench width/depth and scour depth. If applicable, ARM 36.15.102 requires that within a 100-year designated floodway certain pipelines "be buried to a depth at least twice the calculated maximum depth of scour for the base flood." (Also see ARM 36.15.101 for applicable definitions.)

The design of the pipeline along the preferred route for channel crossings will be completed prior to construction based on preconstruction surveys and calculations. The standard design will be to install the pipeline 5 feet below the channel depth for a distance of 15 feet beyond the normal high water banks. Trench width would typically range from 15 to 20 feet at the top of trench and range from 5 to 7 feet at the bottom of the trench depending on trench depth. Soil type and conditions, such as cohesiveness and saturation, and the type of excavation equipment used will also affect trench width and the slope of the sides. Wider trench widths of 30 to 40 feet at the top could be required. Each channel crossing will be evaluated prior to construction in the manner described below and will take into account the hydrologic and hydraulic parameters associated with general scour and channel migration.

Scour - For scour assessment, various methodologies will be applied and are dependant on the composition of the soil and available information at the crossing. The steps are summarized below:

- Every identified crossing will first be screened based on the delineation of the tributary drainage area. Those drainage basins that are less than 10 square miles in area will be determined not to require further evaluation and the minimum pipe burial requirement of 5 feet will be assumed to be adequate for the crossing design.
 - Basin areas will be determined from the available USGS maps, DEM data and aerals. To determine the 100 year return frequency of inflow to rivers and streams, the available National Flood Frequency regression equations will be applied or new projections will be made using the actual USGS Stream Gage data using the Log-Pearson Type III Distribution or Weibell Formula.
- A second screening will include the evaluation for scour to determine if there is potential to require pipe burial below 5 feet in depth.
 - The mean competent velocity methodology will be used for the evaluation of scour for cohesive and non-cohesive soils. This methodology is described fully in Transportation Association of Canada's Guide to Bridge Hydraulics. In addition, the Critical Shear Stress and Maximum Permissible Velocity will be compared for the evaluation of scour for cohesive and non-cohesive soils. These methodologies are outlined in Ven Te Chow's Open Channel Hydraulics. Institutions

Keystone XL Project – Montana Major Facility Siting Act Application

such as the FHWA, USACE, USDA consider the same general method albeit the formula may be different.

- The crossings identified with scour potential will undergo a final evaluation, which may require redesign, to conduct a thorough assessment of the hydrologic and hydraulic condition in order to determine proper pipe depth and length. As discussed below, evaluation may include obtaining detailed cross sections by survey, photos, grab samples, and and/or shallow boreholes to determine subsurface geology.

Stream Meander - The evaluation of stream meander migration will be assessed as follows:

- The initial screening criteria will be a visual inspection of historic and present day aerial photos to determine if significant changes in channel alignment have occurred.
- If changes are observed that potentially may exceed 15 feet in a 50 year pipe service period, additional investigations will be conducted using the circle analysis to determine the appropriate design length required for the crossings.
 - For lateral migration assessment, the methodology as described in the National Cooperative Highway Research Program (NCHRP) Report 533: Handbook for Predicting Stream Meander Migration (Transportation Research Board of the National Academies) will be applied to project the degree of lateral migration. This method involves comparisons of historic and present-day aerial photographs. The stream positions from both the historic and present-day photos are overlain in ArcGIS to estimate the rates of change in the stream position. Circles are used to represent the stream curvature.
- Each crossing will be designed based on the findings of the hydrologic and hydraulic assessments to be performed prior to construction.

Evaluation - The evaluation of scour and stream meander will require collection and analysis of a significant amount of data. Examples of this information are identified below:

- Collection and processing data for the actual engineering evaluation may require a significant amount of time not accounted for in the detailed analysis. Each of the following steps will also require acquisition of appropriate permits and access, as well as mobilization of field crews and equipment.
 - Grab samples may be acquired at major crossings (those that have the potential for significant scour in excess of 5 feet).
 - Boreholes may be acquired near crossings.
 - Cross section survey data for major crossings: 40 – 50 ft upstream of crossing, at the crossing, and downstream of the crossing may also be required.
- An average of 8 hours is spent analyzing each crossing based on the complexity of the crossing and required analysis to finalize the depth and length of the pipe for each crossing.

Because of the site-specific nature of the work, it will not commence until precise crossing locations are determined. It is not considered feasible to conduct these investigations, contact landowners, and impact landowners that are not part of the preferred route nor part of the EIS notification and scoping process crossings on alternative routes.

Keystone XL Project – Montana Major Facility Siting Act Application

Clarification for Section 3.4(7)(a)

DEQ Request:

(7) Social characteristics

(a) current land uses to economic & social activities in the areas

No discussion of social opinions, trends, etc.

Keystone Response:

The social structure of the impacted communities is shaped in part by the rural and remote nature of the project area. Many of the residents are socially isolated and typically have interaction within their own community. From this interaction, the result is generally a common set of values towards land and the community.

Residents often have a lifestyle that is tied to the land via ranching and/or farming, and therefore have a strong conservation ethic based around sustainability. Outside of agriculture, economic opportunities are limited as there are not many large population centers in the project area. The largest cities in the project area are Glendive and Glasgow which provide service and government employment opportunities, as well as options for significant shopping purchases. Nashua, Circle, and Baker also provide limited services and shopping opportunities.

Clarification for Section 3.4(9)(d)

DEQ Request:

(8) Landscape aesthetics

(d) overlay of land areas categorized for visual compatibility.

Keystone Response:

The following tables provide scenic quality ratings by route. The map shows these quality ratings spatially.

In the following tables, scenic quality is rated numerically for each of the 7 factors in the columns of the tables prepared for each of the alternatives. The potential range for most of the factors is either 0 to 5 or 1 to 5 (5 being the highest), but, for cultural modifications, which include any man-caused changes to the natural landscape, the range is -4 to +2 (2 being the highest; 0 indicates modifications add little or no visual variety to the area, and introduce no discordant elements). The higher the total score, the higher the scenic quality for an area. A total score of 11 or less = Class C (relatively low public value), 12 to 18 = Class B (moderate public value), 19 or greater = Class A (high public value).

Clarification for Section 3.7(10)(b)

DEQ Request:

(9) Visual resources and viewer information

(b) visual contrast overlay

Keystone Response:

In combination with photos from 3.7(10)(g), Attachment P, page P-32 to P-64, the following tables provide the visual contrast information by Key Observation Point (KOP) for all three routes.

The contrast ratings were conducted to address the short-term time frame of 5 years. That is, to determine if the proposed pipeline would achieve the requisite VRM class objectives within 5 years of construction. It is assumed that there would be substantially greater visual contrast introduced during construction, but that this would be acceptable as long as progress is made and the objectives are met within 5 years of construction.

Alternative A Visual Contrast Rating

Clarification for Section 3.8(1)(c)(i)(A)&(B)

DEQ Comment:

3.8(1)(c)(i)

Information and mapping based upon 1 or 2 dominant species and 1 or 2 understory species needs to be provided for the impact zones below.

(A) areas within 0.5 mile radius of pump or compressor stations

(B) crossing of streams with fishery value class of I or II or waterways with annual discharge of 1,000 cfs or more.

Keystone Response:

(A) Information and mapping of vegetation within a 0.5 mile buffer of the 12 potential pump station locations along the three proposed routes (A, A1A, and B) were developed following a three-step process.

1) Preliminary boundary delineation using aerial imagery.

2) Helicopter surveys for all three routes followed by ground verification efforts on selected PS sites, and

3) Final mapping.

The first step, preliminary desktop aerial interpretation, occurred during initial land use analysis and identified five plant community types (very low cover grasslands, low/moderate cover grassland, mixed riparian, wetlands and agricultural lands-dry crop) using digital aerial imagery (2006 NAIP 1-meter color imagery and 2005 DOQQ 1-meter color imagery).

Helicopter surveys were conducted in April 2009 for pump stations on all three route alternatives to assign vegetation/land use type. Furthermore, helicopter surveys were also conducted along the major river crossings (Milk River, Missouri River and Yellowstone River). In May 2009, field confirmation of selected sites was performed in order to field check types and develop species lists. Ground verification efforts identified the dominant plants within the upper and lower canopies of the vegetation profile within each plant community. Final mapping followed these efforts.

Very Low Cover and Low/Moderate Cover Grasslands

Within the very low cover and low/moderate cover grasslands graminoids were typically the dominant plants comprising the greatest canopy cover within the potential pump station locations. The dominant species in the very low cover grasslands type include blue grama (*Bouteloua gracilis*), Prairie June grass (*Koeleria macrantha*), western wheatgrass (*Pascopyrum smithii*), and threadleaf sedge (*Carex filifolia*). Associated species include clubmoss (*Saleginella densa*) and Hood's phlox (*Phlox hoodii*). The dominant species encountered within the low/moderate grasslands include western wheatgrass (*Pascopyrum smithii*), blue grama (*Bouteloua gracilis*), green needlegrass (*Nassella viridula*), and Idaho fescue (*Festuca idahoensis*). Other commonly dominant species encountered include Prairie June grass (*Koeleria macrantha*), Sandberg's bluegrass (*Poa secunda*), needle and thread grass (*Hesperostipa comata*), and threadleaf sedge (*Carex filifolia*). Shrub species such as *Symphoricarpos* spp. and *Artemisia frigida* and *Artemisia cana* were also encountered.

Keystone XL Project – Montana Major Facility Siting Act Application

Wetlands

The vegetation of the wetland community is characterized by a moderately dense to dense perennial graminoid layer dominated or codominated by *Carex nebrascensis*. Other graminoid species present are *Carex praegracilis*, *Calamagrostis stricta*, *Deschampsia caespitosa*, *Eleocharis palustris*, *Glyceria striata*, *Juncus balticus*, and *Schoenoplectus pungens*. This type is shown as emergent wetlands (PEM) or forested wetlands (PFO).

Mixed Riparian

Within the mixed riparian plant community the plains cottonwood (*Populus deltoides*) was the dominant overstory with the shrub species silver sage (*Artemisia cana*) and *Symphoricarpos* spp. occupying the understory. The herbaceous plant community includes the species bluejoint reedgrass (*Calamagrostis Canadensis*), Baltic rush (*Juncus balticus*), and sedges (*Carex* spp.).

Agricultural Lands–Dry Crop

Agricultural lands–dry crop plant community had crested wheatgrass (*Agropyron cristatum*) as the dominant plant species with smooth brome (*Bromus inermis*) also occurring. The agricultural lands-dry crop classification also includes dry-land wheat (*Triticum aestivum*) and other crops. These two types are broken into two classes in the tables below.

Agricultural Lands–Irrigated

Agricultural lands-irrigated is typically planted wheat.

Water

Waterbodies are one of three types: ephemeral (EPH), intermittent (INT), and perennial (PER). These are not shown in the vegetation tables below, but are displayed on the maps.

Developed Lands

Developed lands includes commercial (DCOM), residential (DRES), industrial (DIND) as well as right-of-way (DROW) designations. These are not shown in the vegetation tables below, but are displayed on the maps.

Clarification for Section 3.8(1)(c)(iii)(C)

DEQ Request:

3.8(1)(c)(iii)(C) for liquid pipelines, any additional waters where aquatic habitats could be adversely affected by a liquid spill or leak;

Keystone Response:

Attachment D, Section 3 estimates incident frequency conservatively as 1 release in any 1-mile segment every 7,500 years along the Project in Montana. A hypothetical release would have a 50 percent probability of being 3 barrels or less; 35 percent probability of being between 3 and 100 barrels; 10 percent probability of being between 100 and 1,000 barrels; 5 percent probability of being between 1,000 and 10,000 barrels; and a 0.5 percent probability of being more than 10,000 barrels. Please note that an amendment to Attachment D, Section 4 is also included in this submittal.

The method used to respond to Section 3.8(1)(c)(iii)(C) accounts for 100 percent of the alternative routes, and categorizes all portions of the pipeline that cross or are located near a National Hydrography Dataset (NHD)-defined waterway within one of the categories indicating where impacts might possibly occur. A 500 foot buffer along the pipeline on either side of waterways crossed was included as part of the crossing. All portions of the pipeline within ¼ mile of waterways were analyzed for surrounding topography. It was assumed that product could only travel over flat ground for 200 yards, or for up to ¼ mile over steep terrain with slopes greater than 5 percent. Buffers of ¼ mile were transposed on the routes, and slopes within the buffer were analyzed. Portions of pipeline in each simulated catchment within 200 yards, excluding areas with slopes greater than 5 percent, were identified as pipeline segments that could impact aquatic habitats (PSAH).

In order for impacts to occur, the following circumstances must all surround a release and happen at the same time and place: 1) be within a segment that could contribute to a stream; 2) be of a sufficient size to travel overland and reach the waterway; 3) have water flow in the waterway for transport; 4) have presence of aquatic habitat at or downstream from the introduction; and 5) have contaminant in a concentration (release size) great enough to impact the aquatic habitat. It is highly unlikely that all these circumstances would occur at the same time causing an impact to aquatic habitat. Mapbook 8 depicts the reaches of stream that might, although highly unlikely, have aquatic habitat impacted by a release. All these factors are shown in Table 1, which lists the length of each route's PSAH as an indication of the aquatic habitats that could be adversely impacted by a hypothetical release. All route alternatives have 1 percent or less contributing by direct flow to a perennial waterway. The postulated occurrence interval for theoretical impacts occurring in each category of PSAH along each alternative route is also noted by incident magnitude. Table 2 contains examples of calculations used to arrive at the occurrence intervals.

¹ Incident size: Very small=3 barrels; Small=50 barrels; Moderate=1,000 barrels; Large=10,000 barrels.

Occurrence interval calculations account for probability of each spill size (Att. D, Section 3.2), probability of flow in the waterway (Perennials flow 100%, Intermittent flow 50% of time), probability of resources being present (100% Perennial, 20% Intermittent have resources), and probability of spill size traveling overland to waterway (Very small = 5%, Small = 10%, Moderate = 30%, Large = 75%).

Table 2 Examples of Calculations of the Occurrence Intervals by Incident Size

<u>Very Small Size - Overland flow to Intermittent waterway</u>	One incident divided by the following denominator: Total miles (for Route A, 65.8 miles) * probability of a spill (0.000133 incidents/mile*year) * spill size's probability of occurring (very small, 0.5) * spill size's assumed probability of reaching the waterway via overland flow (very small, 0.05) * assumed probability of flow in the waterway (intermittent, 0.5) * assumed presence of a resource downstream in the waterway (intermittent, 0.2). <u>1 incident / (65.8 miles * 0.000133 incidents/mile/year * 0.5 * 0.05 * 0.5 * 0.2) = 45,707 years</u>
---	--

Keystone XL Project – Montana Major Facility Siting Act Application

Table 2 Examples of Calculations of the Occurrence Intervals by Incident Size

Small Size Direct flow to Intermittent waterway	One incident divided by the following denominator: Total miles (for Route A, 48.6 miles) * probability of a spill (0.000133 incidents/mile*year) * spill size's probability of occurring (small, 0.35) * assumed probability of flow in the waterway (intermittent, 0.5) * assumed presence of a resource downstream in the waterway (intermittent, 0.2). $1 \text{ incident} / (48.6 * 0.000133 \text{ incidents/mile/year} * 0.35 * 0.5 * 0.2) = 4,420 \text{ years}$
Moderate Size Overland flow to Perennial waterway	One incident divided by the following denominator: Total miles (for Route A, 1.3 miles) * probability of a spill (0.000133 incidents/mile*year) * spill size's probability of occurring (moderate, 0.1) * spill size's assumed probability of reaching the waterway via overland flow (moderate, 0.3) * assumed probability of flow in the waterway (perennial, 1.0) * assumed presence of a resource downstream in the waterway (perennial, 1.0). $1 \text{ incident} / (1.3 \text{ miles} * 0.000133 \text{ incidents/mile/year} * 0.1 * 0.5 * 1.0 * 1.0) = 192,790 \text{ years}$
Large Size – Direct flow to Perennial waterway	One incident divided by the following denominator: Total miles (for Route A, 0.8 miles) * probability of a spill (0.000133 incidents/mile*year) * spill size's probability of occurring (large, 0.05) * assumed probability of flow in the waterway (perennial, 1.0) * assumed presence of a resource downstream in the waterway (perennial, 1.0). $1 \text{ incident} / (0.8 \text{ miles} * 0.000133 \text{ incidents/mile/year} * 0.05 * 1.0 * 1.0) = 187,970 \text{ years}$

Attachment D, Section 4.2.2.4 discusses the potential impacts to aquatic habitats. **Tables 4-4 through 4-11 of Attachment D** contain details of potential impacts according to stream size and hypothetical release size. Please refer back to **Tables 1 and 2 in Attachment P** pages P-71 to P-81 for descriptions of aquatic habitat, special use sites, and fish distribution in perennial streams near the Keystone XL Project Alternatives.

Montana's Comprehensive Fish and Wildlife Conservation Strategy (MCFWCS) emphasized two aquatic focus areas within the project area, the Lower Missouri River and the Lower Yellowstone River. Portions of Routes A and A1A are in the Lower Missouri River area and a portion of Route B is within the Lower Yellowstone River area. These prairie stream drainages include large perennial warmwater rivers, breaks and coulees, pothole lakes, and intermittent streams (MCFWCS 2005). There are a total of 55 aquatic (2 crayfish, 3 mussel, and 50 fish) species that are found within the Lower Missouri River Focus area and 65 aquatic (1 crayfish, 3 mussel, and 60 fish) species within the Lower Yellowstone River Focus Area (MCFWCS 2005). After meetings between Keystone representatives and Montana Fish, Wildlife, and Parks (MFWP) in 2008 and 2009, the northern redbelly dace x finescale dace and pearl dace were the only species of concern that have the potential to occur within intermittent streams with suitable habitat crossed by the Project.

Conclusion

This conservative analysis of the proposed Project alternatives coupled with the Keystone XL Project Pipeline Risk Assessment and Environmental Consequence Analysis for Montana (Attachment D) demonstrates that the predicted frequency of incidents is very low, the probability of a large spill occurring is very low, and, consequently risk of a release that would impact aquatic habitats is extremely low. Compliance with regulations, application of Keystone's IMPs and Emergency Response Plan (ERP), as well as adherence to safety procedures will help to ensure long-term, environmentally sound, and safe operation of the pipeline.

Clarification for Section 3.8(1)(c)(iv)

DEQ Request:

3.8(1)(c)(iv) for a liquid pipelines facility, a detailed assessment of the consequences of a spill or leak downstream of each crossing of a perennial waterway, including a description of the principal resources that would be affected, the magnitude of the impact to fishery resources and habitat, and a description of proposed spill detection, containment, and cleanup techniques;

Keystone Response:

Table 1 below indicates perennial waterway crossings for each route and the associated resources that could be impacted by a hypothetical release at each crossing along with shading that indicates the magnitude of impacts that might be expected from a hypothetical release. Resources were identified through multiple sources. Fisheries that are downstream of potential hypothetical releases at perennial waterway crossings are the same as those listed in **Attachment P**, pages P-71 to P-81. Public water supply system intakes were identified through data from MDEQ (MDEQ 2009). USGS 24K topographic maps were also utilized in the analysis of resources.

Table 2 below lists streamflow statistics for perennial streams crossed by the alternative routes where gaging station records were available. These perennial streams can be classified according to their average annual flow by the stream categories within Table 4-1 in the Project Pipeline Risk Assessment and Environmental Consequences Analysis for Montana (**Attachment D**).

Attachment D, Section 4.2.2.4 provides information regarding the magnitude of possible impacts to aquatic ecosystems. The magnitude of effects varies with multiple factors, the most significant of which include the amount of material released, the size of the spill dispersal area, the type of crude oil spilled, the species assemblage present, climate, and the spill response tactics employed. If a hypothetical release were to occur along a PSAH to the streams and rivers referenced in **Table 2**, the magnitude of the impacts can be estimated to those specific streams by referencing the average annual flow at the gage (after considering any necessary adjustment for tributaries and/or distance from gage to crossing) to **Attachment D**, Section 4.2.2.4.

Hypothetical release frequency and size is discussed in Chapter 1, Section 1.5.5 of the MFSA application on page 1-34. Hypothetical release detection is described in Chapter 1, Section 1.5.6 on pages 1-34 and 1-35.

Containment and cleanup will be addressed in the Spill Prevention, Control and Countermeasure (SPCC) Plan for construction and in the Emergency Response Plan (ERP) for operations. A draft SPCC Plan was provided in the April 7, 2009 (green) supplemental filing. An outline of the ERP can be found in **Attachment B**. The Keystone XL ERP, which is based on the previously PHMSA- approved Keystone ERP, is under development and will be filed with PHMSA for review prior to operations.

Conclusion

This conservative analysis of the proposed Project alternatives coupled with the Keystone XL Project Pipeline Risk Assessment and Environmental Consequence Analysis for Montana (**Attachment D**) demonstrates that the predicted frequency of incidents is very low, the probability of a large spill occurring is very low, and, consequently, risk of a release that would impact principal resources or fishery resources and habitats is minimal. Compliance with regulations, application of Keystone's Integrity Management Program and ERP, as well as adherence to safety procedures will help to ensure long-term, environmentally sound, and safe operation of the pipeline.

¹ Based on average annual stream flow after considering any necessary adjustment for tributaries and/or distance from gage to crossing where appropriate, or on stream width when no gage data was available.

² Incident size: Very small=3 barrels; Small=50 barrels; Moderate=1,000 barrels; Large=10,000 barrels.

Shading indicates concentrations that could potentially cause acute toxicity to aquatic species according to Attachment D, Table 4-7. The darkest shading represents high probability of acute toxicity (>10 times the toxicity threshold), lighter shading represents moderate probability of acute toxicity (1 to 10 times the toxicity threshold), and unshaded areas represent low probability of acute toxicity (< toxicity threshold).

Occurrence interval based on the conservative overall predicted incident frequency of 0. 000133 incidents/mile*year, projected frequencies of each spill volume (Attachment D, Section 3.2), and calculated with miles of CPS per crossing prior to rounding.

Clarification for Section 3.8(1)(c)(v)

DEQ Request:

3.8(1)(c)(v) for any wetlands or other waterfowl habitat downstream from a river crossing that could be adversely affected by a liquid spill or leak, information on seasonal abundance and species composition of waterfowl populations.

Keystone Response:

Wetlands that have the possibility of being affected by a hypothetical release were identified through GIS analysis of the National Land Cover Dataset (NLCD) 2001. Any areas attributed in the NLCD as wetland land cover was considered; "Emergent Herbaceous Wetlands" and "Woody Wetlands" were both present in the area. Any wetlands over 1 acre surface area and intersecting with the hypothetical release paths, along with additional wetlands identified along possibly affected reaches of the Yellowstone and Missouri rivers were categorized and presented to the MFWP in May 2009 for information on waterfowl species composition and seasonal abundance. Based on the response from MFWP, these data are not available and to provide these data, surveys would need to be conducted during three seasons. MFWP advised that specific data on such waterfowl species and seasonal abundance is not available. General information that is available is provided in the discussion below. Based on this discussion, this item should be deemed complete.

Source: USGS. 2001. National Land Cover Database (NLCD) 2001

The Project is located within the Central Flyway for migrating bird species. Medicine Lake National Wildlife Refuge (NWR), located along and adjacent to routes A and A1A, provides representative information for the seasonal abundance and composition of waterfowl within the Project area. Medicine Lake NWR has long been recognized for its importance to breeding and migrating waterfowl and was the primary reason for the purchase of the refuge in 1935 (USFWS 2009). Most common nesting ducks are mallard, gadwall, northern pintail, northern shoveler, blue-winged teal, and lesser scaup, with a total of 14 species breeding locally (USFWS 2009). More than 300 pairs of Plains Canada geese breed in the refuge complex (USFWS 2009). Spring and fall migrations bring thousands of waterfowl to the refuge, mostly ducks, Canada and white-fronted geese, and tundra swans, with a smaller number of snow geese (USFWS 2009).

Clarification for Section 17.20.815(6)

DEQ Request:

Design capacity and operational characteristics.

Describe design capacity and operational characteristics for associated facilities.

Keystone Response:

The proposed service to Project pump stations are 115 kilovolt (kV) transmission lines, with a proposed transmission structure matching the TP-115; a single pole, horizontal post insulator design.

Three factors are considered in designing a power line. The first is the voltage characteristic during load flow, or voltage drop. This is a combination of the load current and the resistance of the conductor. Though the final conductor size has not been determined for Project power lines, the conductor will have a minimum ampacity of 560 amps. Using that, the maximum load at 115 kilovolts would be 110 megawatts. For all locations, source voltage is the determining factor in the circuits to be used, not load flow. For example, initial load flow calculations indicate the 115 kV circuit will be needed to maintain the voltage regulation (spread between no-load and loaded circuit voltage) to select Project pump stations. Using this voltage will be more economical rather than adding transformation costs.

The second factor is the power limit of the line. Bulletin 62-5 “Electrical Characteristics of AC Transmission Line Designs” (USDA 1976) outlines a parameter called Surge Impedance Loading, or SIL. The published SIL value for the TP-115 structure proposed for the Project is 36 megawatts (MW), which is the optimum load for a line of this design with a distance equal to 300 miles. A line shorter than 300 miles can be loaded more heavily than 36 MW, and a longer line should be loaded less than that. The longest proposed power line within Montana is approximately 50 miles in length. The published SIL would indicate that a 115 kV line would be able to very capably serve the 25 MW Project loads.

Theoretically, the stability (or power) limit for a transmission line is calculated using the following equation:

$$\text{Power Max} = (0.75 * \text{Voltage (in kilovolts)}^2) / \text{line length (in miles)}$$

For a 115 kV circuit, 50 miles in length, that maximum power would be:

- $P_{\text{max}} = (.75 * 115^2) / 50$
- $P_{\text{max}} = 9920 / 50$
- $P_{\text{max}} = 198 \text{ megawatts.}$

Based on the above formulas, the optimum load for the proposed 115 kV lines lies between 36 and 200 MW, depending upon the conductor size chosen. The distances for each of the proposed transmission lines are known factors. Therefore, the conductor size will vary. Based on current estimates, the minimum conductor size will be at least 397 aluminum conductor steel reinforced (ACSR) or larger.

The third factor considered is limitation of motor starting, or flicker, seen by other users of the circuits interconnecting to the power lines for Project pump stations. The current is lower for the 115 kV line, in comparison to a lower voltage circuit. This assists in mitigation of any flicker or disturbance to the line with motor starting. Thus, the 115 kV rating is desirable for these loads, especially if other customers are fed from the same circuit.

Clarification to 75.20.1511(9)

(9) Construction camps

DEQ Comment:

Update requested. Keystone has recently indicated that worked camps are being planned in the areas of Nashua and Baker, Montana. To address this rule, please provide a description of the camps planned for the construction crew, and how they will be operated.

Keystone Response:

Based on an in-depth housing analysis and on updated discussions with construction contractors, Keystone plans to use temporary construction camps. These temporary camps will supplement local housing in remote areas of Montana for the duration of construction in the area. Currently, Keystone is considering two camps in Montana, generally situated at the spread breaks between Spreads 1 and 2 and between Spreads 3 and 4.

Each camp will be designed to house approximately 600 people. Camps will consist of prefabricated, modular, dormitory-style units that include heat and air conditioning systems. Camps typically will include sleeping areas with shared and private baths, craft rooms, recreation facilities, telecommunication/media rooms, kitchen/dining facilities, laundry facilities, security/infirmity unit, offices, and wastewater treatment facilities.

Construction camp sites will be approximately 80 acres each in size, of which 30 acres will be used as a contractor yard and 50 acres will be used as the actual camp site. Within the acreage designated for the camp site, space will also be set aside for RVs. The water, electricity, and wastewater for RVs will be tied into one camp system. Camps will be permitted, constructed, and operated in compliance with applicable county, state, and federal regulations. **Table 1** summarizes the regulations and permits required for construction camps based upon preliminary designs of the camps. Final design will be accomplished after bidding and hiring contractors to build and maintain the camps. Keystone will be responsible for obtaining all permits. Due to the timing of engaging a contractor to build and operate the camps, Keystone will acquire permits based upon a preliminary design for each camp.

Where feasible, potable water will be provided by drilling a well. If an adequate water supply cannot be obtained from the well, water will be provided by municipal sources or trucked to each camp. A wastewater treatment facility will be included in each camp to treat wastewater to meet regulatory standards prior to discharge.

In areas where construction camps are used, camps will include a health, safety and environment program, fire and HAZMAT protection programs (NFPA Level 101), and a vector program. Therefore, strains on the public services in areas where camps are employed would be minimal.

Keystone XL Project – Montana Major Facility Siting Act Application

Table 1 Construction Camp Permits and Regulations

<u>Agency/State</u>	<u>Permit/Discussion</u>
<u>Montana</u>	
<u>Montana DEQ</u>	<u>Public water and sewer (PWS) laws, Title 75, chapter 6, part 1, MCA. Rules at Administrative Rules of Montana (ARM) 17.38 101, and Department Circulars incorporated by reference. Require plan and spec review before construction of a public water or sewer system. Circulars contain design requirements. Requires water quality monitoring of water supply.</u> <u>Sanitation in subdivisions laws, Title 76, Chapter 4, MCA. Rules at ARM Title 17, Chapter 36. If applicable, requirements would be the same as the PWS laws and Circulars for water supply and wastewater. Would require additional review of stormwater systems and solid waste management. (Likely not applicable unless created "permanent" multiple spaces for mobile homes or RVs. 76-4-102(16), MCA.)</u> <u>Water Quality Act Discharge Permits, Title 75, Chapter 5, MCA. ARM 17.30.1022.</u> <u>Air permit for diesel fired generators.</u>
<u>Department of Public Health and Human Services (DPHHS)</u>	<u>Work Camp licensing laws, Title 50, Chapter 52, MCA. Rules at ARM Title 37, Chapter 111, Subchapter 6. Regulations regarding water, sewer, solid waste, and food service. Incorporates DEQ PWS requirements but has additional water and sewer provisions. Administered by DPHHS, Public Health and Safety Division, Communicable Disease Control and Prevention Bureau, Food and Consumer Safety Section.</u>
<u>Counties</u>	<u>Permit required for wastewater systems, Regulations adopted under Section 50-2-116(1)(k), MCA. Adopting state minimum standards promulgated by Board of Environmental Review at ARM Title 17, chapter 36, Subchapter 9. Generally follow state laws for subdivisions, PWS, DEQ-4.</u> <u>Work camp permit required in some counties.</u>

The Project is in the process of identifying existing electric power infrastructure to supply power to each of the construction camps. However, if existing infrastructure is not available, diesel-fired internal combustion engines may be used to supply primary power to one or more of the construction camps. Additionally, even if power line infrastructure to each of the construction camps is available, the Project may install diesel-fired internal combustion engines as emergency back-up generators, to supply power to the camps if electrical power from the local utility is interrupted. To determine preliminary emissions estimates from the diesel-fired generator engines, a worst-case scenario of four, 400-kilowatt generator engines was assumed for installation per camp. This worst-case scenario would occur if electrical power to one of the construction camps was unavailable. Each of the diesel-fired engines would be "Tier 3" certified engines and are assumed to operate 8,760 hours per year. Preliminary estimates of emissions associated with four primary power generators are

Keystone XL Project – Montana Major Facility Siting Act Application

included in [Table 2](#) and preliminary estimates of emissions from one backup generator are included in [Table 3](#).

Table 2 Four Power Generators

<u>Compound</u>	<u>Emission Factor</u>	<u>Units</u>	<u>Hourly (lbs/hr)</u>	<u>Annual (tons/year)</u>

Table 3 One Back-up Generator

<u>Compound</u>	<u>Emission Factor</u>	<u>Units</u>	<u>Hourly (lbs/hr)</u>	<u>Annual (tons/year)</u>
<u>NO_x + NMHC</u>	<u>3.0</u>	<u>g/bhp-hr</u>	<u>3.53</u>	<u>15.45</u>
<u>CO</u>	<u>2.6</u>	<u>g/bhp-hr</u>	<u>3.09</u>	<u>13.52</u>
<u>PM</u>	<u>0.15</u>	<u>g/bhp-hr</u>	<u>0.18</u>	<u>0.77</u>
<u>SO_x</u>	<u>0.054</u>	<u>lb/MMBtu</u>	<u>0.25</u>	<u>1.08</u>
<u>Pb</u>	<u>9.0</u>	<u>lb/10¹² BTU</u>	<u>4.1E-05</u>	<u>1.8E-04</u>

The Project also will be subject to air quality regulatory programs in Montana if generator engines are needed to supply power at one or more of the construction camps.

New Source Performance Standard regulations establish a standard of performance for new, modified, or reconstructed sources, which fall into any specified source category, regardless of geographic location or the existing ambient air quality. The standards define emission limitations for a particular source group. The NSPS potentially applicable to the Project, which may apply to the construction camp generator engines, include Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines, as discussed below.

Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines

In 2006, USEPA promulgated this rule that applies to stationary diesel-fired internal combustion (IC) engines and that sets standards for oxides of nitrogen (NO_x), CO, PM, and non-methane hydrocarbon (NMHC), along with limiting SO₂ emissions through use of lower sulfur fuel. This regulation may apply to the generator engines at the construction camps, depending upon the manufacture dates of the engines. The primary burden of the proposed regulation falls on IC engine manufacturers, rather than on owners/operators, since engine manufacturers must certify their engines to the emission standards.

The ARM, Title 17, lays the framework for the state air quality laws and regulations in Montana. The ARM establishes the legal authority of the MDEQ to enforce the regulations set forth by the Clean Air Act of Montana, Title 75. Chapter 8 of Title 17 of the ARM identifies the air quality regulations that would apply to the generators at the construction camps, if the generators are installed. Specifically, Subchapter 7 includes provisions for the construction and operating permit requirements of air contaminant sources. These regulations would apply if the construction camp generators are installed at construction camps in Montana.

Keystone XL Project – Montana Major Facility Siting Act Application

The diesel-fired generator engines that may be located at one or more of the construction camps in Montana if line power is not acquired will have criteria pollutant emission levels below 100 tpy. Therefore, the construction camps would not be subject to Title V operating permit requirements. However, if the generator engines are located at the construction camps long enough for them to be considered stationary sources, they would be subject to state minor source air permitting requirements. The diesel-fired engines may be subject to Subpart IIII of the NSPS, if the engines are manufactured after the regulatory applicability date as specified in the regulation for that engine power rating. The construction camps will comply with Montana air quality permitting requirements if it is determined that installation of the generator engines at one or more locations is required.

Wastewater will be treated with a system established on the site to handle the anticipated volume of wastewater discharge from the camp and to meet the effluent standards required in each county where the camps are located. The details of the wastewater treatment facilities will be provided once a contractor has been selected.

The camp will require approximately 45,000 gallons of water per day. If water wells cannot be installed or can not provide this volume of water, Keystone will look to nearby municipal systems and purchase the water required.

Clarification for Section 17.20.1512(7)(a-g)

DEQ Request:

7) Detailed Spill Contingency Plan

- a. Immediate Notification Procedures
- b. Type and Location of Emergency Response Personnel and Equipment
- c. Any Mutual Aid Agreements to supply Personnel and Equipment and Respond in the Event of a Spill
- d. Response Procedures
- e. Equipment Testing Procedures
- f. Frequency of Field Training Exercises
- g. Plan Update Procedures

Keystone Response:

7) Detailed Spill Contingency Plan

As an interstate liquids pipeline, Keystone is required by federal regulation to develop a detailed Emergency Response Plan (ERP or Plan) prior to commencing pipeline operations. The Plan must be filed for review with the US Department of Transportation (US DOT), Pipeline and Hazardous Materials Safety Administration (PHMSA). Keystone developed an ERP for the initial Keystone Pipeline project. That ERP was approved by PHMSA in January 2009. Keystone is now in the process of preparing an ERP specifically for the Keystone XL Pipeline. The Keystone XL ERP will utilize the work done on the Keystone ERP to the extent applicable. The Keystone XL ERP also will be customized to include numerous location- and project-specific elements. The Keystone XL ERP will be filed with PHMSA prior to commencing operations. The ERP cannot be filed until such time as final pipeline design is completed and route approvals received so that site specific information can be developed for incorporation into the Plan. Keystone will liaise with state and local officials to ensure coordination with local and state offices of disaster services as the Plan is further developed.

The Keystone XL Project ERP will have five broad components: the Plan itself; resources (equipment, personnel, and contractors); training; continuous improvement; and public awareness. Each component is integral to the build up and success of the program and needs to proceed collectively once implemented.

The overall strategy behind the ERP is to manage risks and be able to address the potential consequences in the event of a release. The ERP needs to satisfy regulatory requirements and be user friendly and practical for operations. The ERP must be understood and implemented by field operations which will be achieved through training programs.

Emergency management will be built into pipeline operations through a series of training exercises that direct operations to test and maintain the ERP on an on-going basis.

The Plan is being developed using proprietary software called “ePlan”. This will mean that the entire Plan will be electronic and revised on a continual basis making the Plan current all the time. Administratively, the Plan will be part of the corporate Emergency Management System.

Keystone XL Project – Montana Major Facility Siting Act Application

The Plan will include Response Zones, notifications, public official listings, contractors, technical response procedures, forms, and other elements.

a. Immediate Notification Procedures

Keystone is required by law to notify immediately the National Response Center (NRC) if an event: (1) violates water quality standards; (2) creates a sheen on water; or (3) causes a sludge or emulsion to be deposited beneath the surface of the water or upon adjoining shorelines (40 CFR Part 112). In addition to the NRC notification, Keystone will make timely notifications to other agencies, including the appropriate local emergency planning committee, sheriff's department, US Environmental Protection Agency (USEPA), and affected landowners.

b. Type and Location of Emergency Response Personnel and Equipment

The specific locations of Keystone's emergency responders and equipment will be determined upon conclusion of the pipeline detailed design and the completion of Keystone's ERP. Keystone will base Company emergency responders consistent with industry practice and in compliance with the applicable regulations, including 49 CFR Parts 194 and 195. Keystone's response time to transfer additional resources to a potential leak site will follow an escalating tier system, with Keystone's initial emergency responders capable of reaching all locations within Montana within 6 hours in the event of a spill. Typically, emergency responders will be based in closer proximity to the following areas:

- Commercially navigable waterways and other water crossings.
- Populated and urbanized areas, and
- Unusually sensitive areas, including drinking water locations, ecological, historical, and archaeological resources.

Consistent with industry practice and in compliance with applicable regulations, the types and amount of emergency response equipment based on worst case discharge volumes that will be pre-positioned for access by Keystone will be determined upon conclusion of the pipeline detailed design and the completion of Keystone's ERP, but prior to commencing line fill.

Emergency response equipment will be strategically situated along the pipeline route. Types of emergency response equipment are detailed below. Keystone will engage a national response contractor who will have access to and be able to provide large quantities of equipment to meet Oil Spill Response Organization (OSRO) requirements. Keystone also will have a number of local contractors available to provide emergency response assistance as required. Finally, Keystone will have a contract Spill Management Team available to respond and assist with incident management in the event of a significant release.

The overall strategy is to purchase and situate enough equipment for a Tier 1 response in each Response Zone. A Tier 1 response means a company leak that can be contained, controlled, and cleaned up using primarily Company personnel within a defined period of time from when a release is discovered, which, according to US Department of Transportation (US DOT) regulations, is 6 to 12 hours, depending on the location. It is important to note that the tiered level of response pertains to time requirements and is completely independent of spill threshold volumes. Although volumes are important for determining the correct amount of equipment needed for the tiered response times, they are not intended to define a spill threshold amount. It is well understood by the US DOT/PHMSA that once a Tier 1 requirement is satisfied, Keystone will cascade equipment to Tiers 2 and 3 until enough equipment is available to respond to the Worst Case Discharge amount.

The equipment will be stored strategically along the pipeline typically in the center of the Response Zone and accessible by Keystone and contract staff.

Keystone XL Project – Montana Major Facility Siting Act Application

Consistent with industry practice and in compliance with the applicable regulations, including 49 CFR Parts 194 and 195, the types of emergency response equipment that will be pre-positioned for access by Keystone are highlighted below:

- Pick-up trucks, one-ton trucks and vans;
- Vacuum trucks;
- Work and safety boats;
- Containment boom;
- Skimmers;
- Pumps, hoses, fittings and valves;
- Generators and extension cords;
- Air compressors;
- Floodlights;
- Communications equipment including cell phones, two way radios and satellite phones;
- Containment tanks and rubber bladders;
- Expendable supplies including absorbent booms and pads;
- Assorted hand and power tools including shovels, manure forks, sledge hammers, rakes, hand saws, wire cutters, cable cutters, bolt cutters, pliers and chain saws;
- Ropes, chains, screw anchors, clevis and other boom connection devices;
- Personnel Protective Equipment (PPE) including rubber gloves, chest and hip waders and H₂S, O₂, LEL and benzene detection equipment; and
- Wind socks, signage, air horns, flashlights, megaphones and fluorescent safety vests.

Additional equipment including helicopters, fixed wing aircraft, all-terrain vehicles (ATV's), snowmobiles, backhoes, dump trucks, watercraft, bull dozers, and front-end loaders may also be accessed depending upon site-specific circumstances. Other types, numbers and locations of equipment will be determined upon conclusion of the pipeline detailed design and the completion of Keystone's ERP.

c. Any Mutual Aid Agreements to Supply Personnel and Equipment and Respond in the Event of a Spill

Keystone will investigate opportunities to form and participate in mutual aid agreements once the pipeline begins operations.

d. Response Procedures

SCADA System

Keystone will be operated from an Operations Control Center (OCC), which will be manned on a 24 (hrs/day) x 7(days/week) basis. Keystone will utilize a Supervisory Control and Data Acquisition (SCADA) system to remotely monitor and control the pipeline system. Keystone's SCADA system will include:

- Redundant fully functional backup OCC available for service at all times;
- Automatic features installed as integral components within the SCADA system to ensure operation within prescribed pressure limits; and
- Additional automatic features installed at the local pump station level also will be utilized to provide pipeline pressure protection in the event communications with the SCADA host are interrupted.

Leak Detection Systems

Keystone will have a number of complimentary leak detection methods and systems available within the OCC. These methods and systems are overlapping in nature and progress in leak detection thresholds.

- The first leak detection method is remote monitoring performed by the OCC Operator. Remote monitoring consists primarily of pressure and flow data received from pump stations and valve sites fed back to the OCC to detect leaks down to approximately 25 percent – 30 percent of pipeline flow rate.
- Next are software based volume balance systems that monitor injection and delivery volumes. These systems are typically able to detect leaks down to approximately 5 percent of pipeline flow rate.
- Next are Computational Pipeline Monitoring or model based leak detection systems that break the pipeline system into smaller segments and monitor each of these segments on a mass balance basis. These systems compensate for line pack and are typically capable of detecting leaks down to a level approximately 1.5 percent to 2 percent of pipeline flow rate.
- Finally, we will use direct observation methodologies, which include aerial patrols, ground patrols and public and landowner awareness programs that are designed to encourage and facilitate the reporting of suspected leaks and events that may suggest a threat to the integrity of the pipeline.

Emergency Response

In the event Keystone suspects a leak or a leak is reported to the OCC, Keystone would respond with an emergency pipeline shutdown. This would involve stopping all operating pumping units at all pump stations. Depending on the flow rate at the time of the incident this would mean stopping two to three pumping units at each of Keystone's 39 pumping stations in the US and Canada. This line shutdown is estimated to take approximately 9 minutes. Once all the operating pumping units have been shut down, the OCC Operator would close the sectionalizing or isolation valves in the vicinity of the leak to limit any further draindown at the leak site. Closure of these isolation valves would take an additional 3 minutes. Therefore, from when the leak was reported or alarm received, it would take approximately 12 minutes to shut down and isolate the pipeline. For purposes of estimating worst case spill volumes, however, Keystone has assumed an additional 10 minute period, which is the maximum period an operator is allotted to verify the condition and begin to shut down the affected segment of pipe.

The on-call response designate will be required to respond to and verify an incident. Once the OCC notifies the individual and an assessment of the probability and risk is established, field personnel may elect to dispatch other resources as soon as practical. It is recommended that each truck contain the basic oil spill response equipment such as absorbent boom, rakes, shovels, safety equipment, road barricades etc. The exact first responder equipment strategy is in the developmental stage.

It is anticipated that once the call is received, on-call personnel should respond and arrive on-site within 4 hours. Keystone is required by 49 CFR Part 194 to calculate Worst Case Discharge and address response and mitigative measures within each Response Zone.

Keystone will use environmental information collected during the application process and incorporate response and mitigative measures in the ERP. In addition, an aerial reconnaissance of the route will be completed to verify this information and develop site-specific Tactical Plans for those areas requiring additional details pertaining to an emergency event.

One of the most critical aspects of an emergency is communication and site management. While Keystone will send first responders and verifiers to the site, a mobile command post is recommended to act as a communication link between the site and the Emergency Operations Center. It is envisioned that this will be handled by an outside contractor that can arrive on-site within 12 hours. We have included a very small office inside the 34 foot trailers which would include basic communication equipment including satellite phones.

Keystone XL Project – Montana Major Facility Siting Act Application

Keystone will maintain personnel on-call on a 24(hrs/day) x 7(days/week) basis. These first responders will consist of both employees and contract personnel and will be based at various locations along the length of the pipeline.

The number of emergency responders comprising specific response teams will be determined upon completion of Keystone's ERP. Emergency responders will meet or exceed the requirements of 49 CFR Part 194.115.

Typically, emergency response teams would be comprised of Hazardous Waste Operations and Emergency Response (HAZWOPER) trained personnel as follows:

Tier 1: 8 HAZWOPER trained personnel (includes Emergency Site Manager and Command Post Safety Officer).

Tier 2: 12 HAZWOPER trained personnel.

Tier 3: 24 HAZWOPER trained personnel.

Responders will be dispatched from multiple locations and will have access to alternative means of transportation if weather or other conditions limit access. Alternative means of transportation will include fixed wing aircraft, helicopter, boats and other watercraft, all terrain vehicles, and snowmobiles.

Following execution of the emergency pipeline shutdown, the OCC operator will perform internal notifications as described in the ERP and dispatch first responders to the location identified. Key individuals would then be notified and Keystone's ERP activated as follows:

First Responder

- Notification of potential spill and dispatch received from OCC;
- Spill verified;
- Notification of Emergency Services, if required; and
- Verify with OCC:
 - Pipeline shutdown and status;
 - Pipeline segment isolation; and
- Regional EOC Manager and Qualified Individual (QI) notified.

Regional EOC Manager (QI)

- Notification received from OCC;
- Notification of spill details received from First Responder;
- Oil spill response plan activated;
- Emergency Site Manager (QI) notified;
- Regional EOC activated
- Mobilize response resources requested by Emergency Site Manager (QI);
- Corporate EOC Manager contacted; and
- Agency contacts including the National Response Center and other state and local agencies contacted.

Keystone XL Project – Montana Major Facility Siting Act Application

Incident Commander

- Notification received from Regional EOC Manager (QI);
- On-site First Responder contacted to obtain briefing on spill;
- On-site Command Post activated;
- Regional EOC advised of resource requirements; and
- First Responder relieved.

Response efforts are first directed to preventing or limiting any further contamination of the waterway, once any concerns with respect to health and safety of the responders have been addressed. This is typically accomplished primarily with containment booms and berms. The Incident Commander assumes responsibility for selecting the appropriate locations for construction of berms and deployment of booms as well as communicating any additional resource requirements to the EOC Manager.

Efforts are initially directed toward containing any spilled product on land prior to it reaching the waterway. With the approval of authorities having jurisdiction, activities such as digging ditches and building berms would be undertaken on the down slope of the spill site, to prevent any overland flow of spilled product from entering the waterway. In some cases it may be possible to use a combination of ditches and berms to divert the overland flow of spilled product to a collection point.

To contain the spilled product once it has reached the waterway, efforts are typically directed toward the deployment of containment boom as close as practical and safe downstream of the spill location. With the approval of the authorities having jurisdiction, the Incident Commander assumes responsibility and a tactical plan is developed for selecting a suitable location for the deployment of containment booms, based upon the waterway site-specific conditions, including flow velocity and avoidance of rapids and falls to ensure the effectiveness of the containment booms.

Product is typically recovered from the surface of water and transferred to containment facilities by a combination of mechanical skimming, vacuum recovery, and sorbent materials. Typical methods for the recovery and transfer to containment facilities for product spilled on land include vacuum recovery and sorbent materials.

The cleaning of shorelines and other affected natural or manmade structures is typically performed by traditional methods including wiping, hot water and low or high pressure wash down and the use of surfactants and emulsifiers or other agents. Water and other liquids used for wash down purposes for onshore applications are typically contained and collected using a combination of ditches and berms as described above. All site-specific cleaning methods and materials to be utilized are subject to the approval of the authorities having jurisdiction.

Product laden soils are typically either removed or treated with bioremediation in the event such intrusive cleanup techniques are not appropriate. These and other methods of cleanup including natural recovery, burning, dispersants, and other chemical usage can be considered in accordance with and at the discretion of the authorities having

Consistent with industry practice and in accordance with regulations including 49 CFR Part 194.115, Keystone's response time to transfer such additional resources to a potential leak site will follow an escalating or tier system. Dependant upon the nature of site specific conditions and resource requirements, Keystone will meet or exceed the following requirements, along the entire length of the pipeline system:

Keystone XL Project – Montana Major Facility Siting Act Application

<u>49 CFR Part 194</u>	<u>Tier 1 Resources</u>	<u>Tier 2 Resources</u>	<u>Tier 3 Resources</u>
<u>High volume area¹</u>	<u>6 hours</u>	<u>30 hours</u>	<u>54 hours</u>
<u>All other areas</u>	<u>12 hours</u>	<u>36 hours</u>	<u>60 hours</u>

¹ High volume area means an area with an oil pipeline having a nominal outside diameter of 20 inches or more, crosses a major river or other navigable waters, which, because of the velocity of the river flow and vessel traffic on the river, would require a more rapid response in the case of a worst-case discharge or the substantial threat of such a discharge.

Tier 1, 2, and 3 resources will typically include equipment as described above, along with additional HAZWOPER trained response personnel, as required to effectively respond to site specific conditions and as directed by the Incident Commander.

The primary task of the Tier 1 response team is to minimize the spread of product on the ground surface or water in order to protect the public and unusually sensitive areas, including ecological, historical, and archaeological resources and drinking water locations. The Incident Commander will make an assessment of the site-specific conditions, such as:

- The nature of the spilled product;
- Source of the spill;
- Direction(s) of spill migration;
- Known or apparent impact of subsurface geophysical feature that may be affected;
- Overhead and buried utility lines, pipelines, etc.;
- Nearby population, property or environmental feature that may be affected; and
- Concentration of wildlife and breeding areas.

The Incident Commander will request additional resources in terms of personnel, equipment and materials, from the Tier 2 and, if necessary, the Tier 3 response teams. Once containment activities have been successfully concluded efforts are directed toward the recovery and transfer of free product. Site cleanup and restoration activities follow, all of which are conducted in accordance with the authorities having jurisdiction.

Keystone will utilize both employees and contractors as emergency responders within its initial response efforts in the event of a pipeline spill. In the case of contractors and other spill response organizations, Keystone will have agreements in place identifying and ensuring the availability of the specified personnel, consistent with industry practice and in compliance with the applicable regulations, including 49 CFR Parts 194 and 195.

e. Equipment Testing Procedures

Emergency response equipment will be maintained and tested in accordance with manufacturers recommendations. Problems and deficiencies will be immediately corrected.

Keystone XL Project – Montana Major Facility Siting Act Application

f. Frequency of Field Training Exercises

Emergency Response Program training will include a combination of regulatory compliance and technical training. To achieve regulatory compliance, Keystone will ensure its employees have all mandatory training, including becoming Qualified Individuals and HAZWOPER compliant. Other regulatory requirements will be included in a regular training schedule for operations personnel.

From a technical training perspective, field technicians and managers will be participating in water-based spill response scenarios on an annual basis. Other training elements will be documented in the ERP and be implemented according to the prescribed regulatory agenda. Emergency response agencies and public officials will be invited to observe the field exercises. Staff also will be trained on Incident Command System levels 100/200 and some key staff also will be trained in ICS 300. The Incident Command System is a prescriptive system of responding and managing incidents. Technical staff will be completing ICS 100/200, while management will be completing ICS 300. Training includes class room lectures, table top exercises, on-call drills, field deployment on both land and water, and mutual aid participation.

It is recommended that each region complete at least five exercises per response zone annually. These include a water based drill, table top exercises, dry land deployments, attendance at mutual aid events, etc.

The positions and training requirement for on-site personnel have been identified as follows:

<u>Position</u>	<u>Specialized Training to Meet Oil Spill Response Duties</u>
<u>First Responders</u>	<u>Hazardous Waste Operations and Emergency Response (HAZWOPER) training to Hazmat Technician Level 3 with annual refresher, as required</u> <u>Keystone Emergency Management System (EMS) training</u> <u>National Fire Protection Association (NFPA) training</u>
<u>Emergency Site Manager – Qualified Individual</u>	<u>HAZWOPER training to Hazmat Level 4 Specialist with annual refresher, as required</u> <u>ICS Communication training</u> <u>Keystone EMS training</u> <u>NFPA training</u>
<u>Command Post Media</u>	<u>Keystone EMS training</u> <u>Keystone Media Relations training</u>
<u>Command Post Safety</u>	<u>Keystone EMS training</u> <u>Advanced safety related training</u>
<u>Command Post Documentation</u>	<u>Keystone EMS training</u>
<u>Command Post Site Security</u>	<u>Keystone EMS training</u>
<u>Command Post Resource Mobilization</u>	<u>Keystone EMS training</u>
<u>Command Post Technical</u>	<u>Keystone EMS training</u>
<u>Command Post Staging Leader</u>	<u>Keystone EMS training</u>
<u>Regional EOC Resource Mobilization</u>	<u>Keystone EMS training</u>

Keystone XL Project – Montana Major Facility Siting Act Application

<u>Position</u>	<u>Specialized Training to Meet Oil Spill Response Duties</u>
<u>Regional EOC Community Evacuation Leader</u>	<u>Keystone EMS training</u>
<u>Regional EOC Administration Support</u>	<u>Keystone EMS training</u>

g. Plan Update Procedures

The Plan is being developed using proprietary software called ePlan. This will mean that the entire Plan will be electronic and revised on a continual basis making the Plan current all the time. Administratively, the Plan will be part of the corporate IMS System.

Response to SIR-1.42

DEQ Request:

(xii) noise, radio, and television interference and electric effects

SIR-1.42: How many residences are located within 500 feet of the associated power lines? Would noise, radio, and television interference, and electrical effects be an issue?

Keystone Response:

See revised Attachment O for the number of residences within 500 feet of the alternative power line routes.

Power Provider Practices – Routing and siting information related to electromagnetic and inductive mitigation on the 115 kV power lines and radio communication serving the Keystone XL Pipeline is provided below.

Electromagnetic induction does occur from power lines. The potential radio and television interference, as well as, noise interference, is mitigated by keeping the power line located away from residences (500 feet minimum, if possible). The routing of the power line is done to keep parallel metallic plant (pipelines, metallic cable, fences) at a minimum. On fences, when paralleling the power line, the metallic wire is grounded (driven ground electrode) at least four times per mile. When crossing fences, the metallic wire is grounded using a 5 foot (minimum) ground electrode. Whenever possible a 100 foot right-of-way for the 115 kV power line will be obtained to minimize any future installation of facilities that could be affected by induction.

There are three potential influences on a communication (metallic) plant in the vicinity of a power line. These are inductive influence, coupling, and susceptiveness. The power providers will work closely with sister utilities to determine the route of existing cable plant. Routing takes into account other utilities and keeps separation between the two different types of plant. Montana state law requires that the project engineer obtain as-built information from other utilities. This allows the design engineer the ability to mitigate inductive influences, to the best of their ability. Avoiding paralleling facilities for long distances (over ten miles) is one method of reducing the susceptiveness to communication plant. Shielded telephone cables reduce coupling with nearby power lines. This helps to reduce coupling caused by close spacings.

Harmonic and waveform distortion may occur due to rectifier action of solid-state motor speed controllers. Harmonic mitigation measures are required on all large loads. Experience with the Express Pipeline indicates that when the harmonic filters tripped off line, noise built to levels that effectively shut down the telephone communications. Close cooperation between the consumers (large motor loads) and the power providers will mitigate such harmonic potential. Harmonic filters will be required, based upon measured system harmonic influence levels.

No impacts are expected from the radio communication systems at the Project facilities with regards to electrical and magnetic fields. The only electromagnetic field emitted from the radio antenna is the normal radio frequency signal as licensed by the FCC.

The C-filter on communication systems eliminates the 60 Hz induced noise, but not the harmonics on a telephone system. The system is terminated in delta – wye configurations. This keeps the phase currents relatively balanced. Mitigation efforts on the distribution circuits will include phase balancing.

Power line Radio Frequency Interference (RFI) is usually caused by sparking (arcs). Typically this is caused by loose hardware.

Power lines associated with the Project will have with similar specifications as those analyzed for the Bonneville Power Administration EIS for the construction of a 115 kV circuit from Libby to Troy, Montana (BPA

Keystone XL Project – Montana Major Facility Siting Act Application

2008). The cooperative's proposed electric service facilities for the Keystone XL pipeline will be nearly identical to the BPA single-pole construction. For their transmission line, BPA calculated typical magnetic and electric field strengths. Because no national standards for EMF are in place, industry practice is to limit EMF exposure at or below those in a typical house. As shown in the following figure, at 40 feet from the power centerline, the electric and magnetic field levels calculated for that 115 kV transmission line are equal to or less than this level; therefore, based on power lines with similar specifications, EMF levels will be at or below acceptable values at 40 feet from the transmission centerline. If required by DEQ, the cooperatives can commit to calculate the EMF fields using the BPA Corona and Field Effects Program (USDOE).

2008. Bonneville Power Administration (BPA). 2008. Rebuild of the Libby (FEC) to Troy Section of Bonneville Power Administration's Libby to Bonners Ferry 115-kilovolt Transmission Line Project; Final Environmental Impact Statement. DOE/EIS - 0379. May 2008.

As stated in the Clarification for Section 3.6(7)(c), every effort is made to maintain a minimum clearance of 500 feet to the extent practical, but never less than 100 feet at these locations. Maintaining a minimum of 100 feet from residences will ensure there will be no EMF effects noticed by residents within their homes.

The power provider design uses spring washers to keep hardware tight. Conductor supports use trunion clamps and AGS factory preformed clamps to keep the conductor and support clamps with a firm contact between the two entities at all times, to mitigate arcing sources. At the 115 kV level, corona is usually not a major issue. Corona in itself is not a major source of RFI. Defective lightning arrestors also contribute to RFI. The power providers use a static conductor at the top of the pole to mitigate lightning caused flashovers. Lightning arrestors are limited to the stations where major equipment is located.

These are some of the measures that are incorporated in the line design to minimize the inductive and noise causing potential to communication and other affected facilities.

The radio communication systems at the Project Facilities will operate on specific frequencies licensed by the FCC. This minimizes the risk of any interference with radio, television or any other communication system in the area as well as providing for a process if any interference should occur.

Response to SIR-1.43

DEQ Request:

SIR-1.43: Text on page 4-181, section 4.5.1.6 says one of the avoidance areas was state land. For what reason did you avoid state land?

Keystone Response:

The reference to avoiding state land was inadvertently included in the paragraph in question. A significant amount of state lands are crossed by the proposed routes. Consistent with MCA 75-20-301(1)(h), the use of public lands for the location of the facility was evaluated by Keystone, and public lands were selected where their use was as economically practicable as the use of private lands. Routing was developed through processes identified in Section 4.0. Public lands were crossed by route alternatives; however, consistent with the “economically practicable” provision, preferentially crossing public lands for the sole purpose of maximizing presence on these lands was considered to be less crucial than producing the most constructible and direct route. Crossing public lands in some areas offered more potential for environmental effects or constructability issues, or resulted in a longer route. Therefore, in these cases, opportunities to avoid private lands by ‘stitching’ across public lands were not preferable.

While Keystone believes it has appropriately considered public lands in route development, at DOS and MDEQ’s request, Keystone has generated additional alternatives using a GIS model and associated data layers as outlined in DOS DR #1. These alternatives along with the previous alternatives were reevaluated utilizing the same level of data on each route alternative so an equal comparison was made to each alternative and the preferred route selected. This information was provided to MDEQ August 17, 2009.

Clarification for Section 3.8(1)(i)

DEQ Request:

- (i) Overlay to map and electronic equivalent required by section 3.6(2) indicating discharge points.

Specified discharge points for hydrostatic discharges were not listed nor were landowners, water supply wells, and the information describing existing ground water quality and uses within 1 miles of the discharge.

Keystone Response:

Table 1: Potential Sites for Discharge of Hydrostatic Test Water in Montana, provides a listing of probable areas for dewatering. These locations are based on best available information at this time. Final dewatering locations will be determined once the hydrostatic test contractor is selected and presents a hydrostatic test plan to Keystone. **Table 2:** Wells, Ground Water Quality and Water Uses within One Mile of Potential Hydrostatic Test Dewatering Locations, provides water supply wells within one mile of sites. It also provides information on ground water quality and groundwater uses where available. Keystone submits that data provided herewith should be adequate to justify a completeness determination with respect to this item.

Following **Table 2** are two sets of ground water quality reports. The ground water quality well identification numbers listed in **Table 2** were entered into web databases and the reports downloaded where available. Where groundwater quality reports are available, these wells are in bold and italics in **Table 2**. USGS ground water quality reports are first and the Montana Groundwater Information Center (GWIC) water quality reports follow. Where specific ground water quality data is not available, it has been more generally discussed in Chapter 4, Section 4.3.5 of the KXL MFSA application.

Background:

In order to create **Table 2**, the following data sets were downloaded:

Point of Diversion (POD) wells and Water Rights - Place of Use (POU) data was available from the Montana Department of Natural Resources and Conservation: Water Resources Division. Data were downloaded from: <ftp://nris.mt.gov/dnrc/>

Well information was downloaded from a number of sources:

National Water Information System (NWIS) wells were downloaded from a web database with latitude/longitude and converted into a shapefile: http://waterdata.usgs.gov/nwis/gw#top_of_page

GWIC well data was downloaded from: <http://nris.mt.gov/nsdi/nris/shape/gwicwells.zip>

Other wells were downloaded for a web database by downloading by county, combining tables and converting into a shapefile. This site has well data from several agencies: <http://nris.mt.gov/Apps/WQProject/watermain.asp>

USGS Groundwater quality reports were downloaded from: http://waterdata.usgs.gov/mt/nwis/annual?referred_module=gw&search_criteria=search_site_no&search_criteria=site_tp_cd&submitted_form=introduction

GWIC ground water quality reports were downloaded from: <http://mbmggwic.mtech.edu/sqlserver/v11/help/go/signin.asp>

Note: There is little groundwater information available for Routes A and A1A due to the high porosity of underlying strata. Groundwater along both of these routes will likely be found very deep and it is unlikely that aquifers are present due to high porosity. Discharge of hydrostatic test water shall be conducted at least a half mile from all streams to allow for recharge. However, if dewatering is conducted too far from the source it will filter down into the groundwater table. A buffer will be needed to allow for test water to seep into the ground and recharge adjacent streams. The discharge of test water will be left to the discretion of the Environmental Inspector.

Note: Well ID numbers in bold and italics indicate those wells for which groundwater quality reports are available from USGS and/or GWIC. These reports follow Table 2.

Keystone XL Project – Montana Major Facility Siting Act Application

USGS Ground Water Quality Reports

File created on 2009-05-11 13:26:58 EDT

U.S. Geological Survey

This file contains selected water-quality data for stations in the National Water Information System water-quality database. Explanation of codes found in this file are followed by the retrieved data.

The data you have secured from the USGS NWISWeb database may include data that have not received Director's approval and as such are provisional and subject to revision.

The data are released on the condition that neither the USGS nor the United States Government may be held liable for any damages resulting from its authorized or unauthorized use.

To view additional data-quality attributes, output the results using these options: one result per row, expanded attributes. Additional precautions are at: <http://waterdata.usgs.gov/nwis/qwdata?help>

						Zirconium (Zr):	NR

Field Chemistry and Other Analytical Results

**Total Dissolved Solids (mg/L): 1,562.300		Field Hardness as CaCO3 (mg/L):	NR	Ammonia (mg/L):	NR
**Sum of Diss. Constituents (mg/L): 2,166.600		Hardness as CaCO3: 61.500		T.P. Hydrocarbons (µg/L): NR	
Field Conductivity (µmhos):	2350	Field Alkalinity as CaCO3 (mg/L):	NR	PCP (µg/L): NR	
Lab Conductivity (µmhos):	2321	Alkalinity as CaCO3 (mg/L): 976.82		Phosphate, TD (mg/L as P): NR	
Field pH:	NR	Ryznar Stability Index: 6.933		Field Nitrate (mg/L): NR	
Lab pH:	8.15	Sodium Adsorption Ratio: 32.402		Field Dissolved O2 (mg/L): NR	
Water Temp (°C):	10.5	Langlier Saturation Index: 0.608		Field Chloride (mg/L): NR	
Air Temp (°C):	NR	Nitrite (mg/L as N): NR		Field Redox (mV): NR	
		Hydroxide (mg/L as OH): NR			

Notes

Sample Condition: SHALLOW GW 048*WATER WAS BROWN*

Field Remarks:

Lab Remarks:

Explanation: mg/L = milligrams per Liter; µg/L = micrograms per Liter; ft = feet; NR = No Reading in GWIC

Qualifiers: A = Hydride atomic absorption; E = Estimated due to interference; H = Exceeded holding time; K = Na+K combined; N = Spiked sample recovery not within control limits; P = Preserved sample; S = Method of standard additions; * = Duplicate analysis not within control limits; ** = Sum of Dissolved Constituents is the sum of major cations (Na, Ca, K, Mg, Mn, Fe) and anions (HCO3, CO3, SO4, Cl, SiO2, NO3, F) in mg/L. Total Dissolved Solids is reported as equivalent weight of evaporation residue.

Disclaimer

These data represent the contents of the GWIC databases at the Montana Bureau of Mines and Geology at the time and date of the retrieval. The information is considered unpublished and is subject to correction and review on a daily basis. The Bureau warrants the accurate transmission of the data to the original end user. Retransmission of the data to other users is discouraged and the Bureau claims no responsibility if the material is retransmitted.

		Hydroxide (mg/L as OH):	NR	

Additional Parameters

Iron Tr (mg/L-Fe) 0.050 Sulfide Total(mg/L-S) L.10

Notes

Sample Condition:

Field Remarks: NGP-307 * FLOWING WELL * SAMPLE TAKEN IN BARN AFTER SUB. PUMP AND TANK * WELL SOUTH OF HOUSE AND BARN *

Lab Remarks:

Explanation: mg/L = milligrams per Liter; µg/L = micrograms per Liter; ft = feet; NR = No Reading in GWIC

Qualifiers: A = Hydride atomic absorption; E = Estimated due to interference; H = Exceeded holding time; K = Na+K combined; N = Spiked sample recovery not within control limits; P = Preserved sample; S = Method of standard additions; * = Duplicate analysis not within control limits; ** = Sum of Dissolved Constituents is the sum of major cations (Na, Ca, K, Mg, Mn, Fe) and anions (HCO3, CO3, SO4, Cl, SiO2, NO3, F) in mg/L. Total Dissolved Solids is reported as equivalent weight of evaporation residue.

Clarifications and Responses to Supplemental Information Requests

September 2009 Filing

Keystone XL Project – Montana Major Facility Siting Act Application

|

Response to SIR-1, Section 17.20.1511(7)(b and c)

DEQ Request:

b) Estimates of trench width

Provide the width that the burial depth would be carried laterally to account for lateral stream channel migration.

2/23/09 – DEQ Incomplete. Provide the width that the burial depth would be carried laterally to account for lateral stream channel migration. This information is needed for analyses of impacts.

c) Estimates of scour depth

Keystone Response:

Keystone will comply with applicable requirements for trench width/depth and scour depth. If applicable, ARM 36.15.102 requires that within a 100-year designated floodway certain pipelines "be buried to a depth at least twice the calculated maximum depth of scour for the base flood." (Also see ARM 36.15.101 for applicable definitions.)

The design of the pipeline along the preferred route for channel crossings will be completed prior to construction based on preconstruction surveys and calculations. The standard design will be to install the pipeline 5 feet below the channel depth for a distance of 15 feet beyond the normal high water banks. Trench width would typically range from 15 to 20 feet at the top of trench and range from 5 to 7 feet at the bottom of the trench depending on trench depth. Soil type and conditions, such as cohesiveness and saturation, and the type of excavation equipment used will also affect trench width and the slope of the sides. Wider trench widths of 30 to 40 feet at the top could be required. Each channel crossing will be evaluated prior to construction in the manner described below and will take into account the hydrologic and hydraulic parameters associated with general scour and channel migration.

Scour - For scour assessment, various methodologies will be applied and are dependant on the composition of the soil and available information at the crossing. The steps are summarized below:

- Every identified crossing will first be screened based on the delineation of the tributary drainage area. Those drainage basins that are less than 10 square miles in area will be determined not to require further evaluation and the minimum pipe burial requirement of 5 feet will be assumed to be adequate for the crossing design.
 - Basin areas will be determined from the available USGS maps, DEM data and aeriels. To determine the 100 year return frequency of inflow to rivers and streams, the available National Flood Frequency regression equations will be applied or new projections will be made using the actual USGS Stream Gage data using the Log-Pearson Type III Distribution or Weibell Formula.
- A second screening will include the evaluation for scour to determine if there is potential to require pipe burial below 5 feet in depth.
 - The mean competent velocity methodology will be used for the evaluation of scour for cohesive and non-cohesive soils. This methodology is described fully in Transportation Association of Canada's Guide to Bridge Hydraulics. In addition, the Critical Shear Stress and Maximum Permissible Velocity will be compared for the evaluation of scour for cohesive and non-cohesive soils. These methodologies are outlined in Ven Te Chow's Open Channel Hydraulics. Institutions

Keystone XL Project – Montana Major Facility Siting Act Application

such as the FHWA, USACE, USDA consider the same general method albeit the formula may be different.

- The crossings identified with scour potential will undergo a final evaluation, which may require redesign, to conduct a thorough assessment of the hydrologic and hydraulic condition in order to determine proper pipe depth and length. As discussed below, evaluation may include obtaining detailed cross sections by survey, photos, grab samples, and and/or shallow boreholes to determine subsurface geology.

Stream Meander - The evaluation of stream meander migration will be assessed as follows:

- The initial screening criteria will be a visual inspection of historic and present day aerial photos to determine if significant changes in channel alignment have occurred.
- If changes are observed that potentially may exceed 15 feet in a 50 year pipe service period, additional investigations will be conducted using the circle analysis to determine the appropriate design length required for the crossings.
 - For lateral migration assessment, the methodology as described in the National Cooperative Highway Research Program (NCHRP) Report 533: Handbook for Predicting Stream Meander Migration (Transportation Research Board of the National Academies) will be applied to project the degree of lateral migration. This method involves comparisons of historic and present-day aerial photographs. The stream positions from both the historic and present-day photos are overlain in ArcGIS to estimate the rates of change in the stream position. Circles are used to represent the stream curvature.
- Each crossing will be designed based on the findings of the hydrologic and hydraulic assessments to be performed prior to construction.

Evaluation - The evaluation of scour and stream meander will require collection and analysis of a significant amount of data. Examples of this information are identified below:

- Collection and processing data for the actual engineering evaluation may require a significant amount of time not accounted for in the detailed analysis. Each of the following steps will also require acquisition of appropriate permits and access, as well as mobilization of field crews and equipment.
 - Grab samples may be acquired at major crossings (those that have the potential for significant scour in excess of 5 feet).
 - Boreholes may be acquired near crossings.
 - Cross section survey data for major crossings: 40 – 50 ft upstream of crossing, at the crossing, and downstream of the crossing may also be required.
- An average of 8 hours is spent analyzing each crossing based on the complexity of the crossing and required analysis to finalize the depth and length of the pipe for each crossing.

Because of the site-specific nature of the work, it will not commence until precise crossing locations are determined. It is not considered feasible to conduct these investigations, contact landowners, and impact landowners that are not part of the preferred route nor part of the EIS notification and scoping process crossings on alternative routes.

Keystone XL Project – Montana Major Facility Siting Act Application

Clarification for Section 3.4(7)(a)

DEQ Request:

(7) Social characteristics

(a) current land uses to economic & social activities in the areas

No discussion of social opinions, trends, etc.

Keystone Response:

The social structure of the impacted communities is shaped in part by the rural and remote nature of the project area. Many of the residents are socially isolated and typically have interaction within their own community. From this interaction, the result is generally a common set of values towards land and the community.

Residents often have a lifestyle that is tied to the land via ranching and/or farming, and therefore have a strong conservation ethic based around sustainability. Outside of agriculture, economic opportunities are limited as there are not many large population centers in the project area. The largest cities in the project area are Glendive and Glasgow which provide service and government employment opportunities, as well as options for significant shopping purchases. Nashua, Circle, and Baker also provide limited services and shopping opportunities.

Clarification for Section 3.4(9)(d)

DEQ Request:

(8) Landscape aesthetics

(d) overlay of land areas categorized for visual compatibility.

Keystone Response:

The following tables provide scenic quality ratings by route. The map shows these quality ratings spatially.

In the following tables, scenic quality is rated numerically for each of the 7 factors in the columns of the tables prepared for each of the alternatives. The potential range for most of the factors is either 0 to 5 or 1 to 5 (5 being the highest), but, for cultural modifications, which include any man-caused changes to the natural landscape, the range is -4 to +2 (2 being the highest; 0 indicates modifications add little or no visual variety to the area, and introduce no discordant elements). The higher the total score, the higher the scenic quality for an area. A total score of 11 or less = Class C (relatively low public value), 12 to 18 = Class B (moderate public value), 19 or greater = Class A (high public value).

Clarification for Section 3.7(10)(b)

DEQ Request:

(9) Visual resources and viewer information

(b) visual contrast overlay

Keystone Response:

In combination with photos from 3.7(10)(g), Attachment P, page P-32 to P-64, the following tables provide the visual contrast information by Key Observation Point (KOP) for all three routes.

The contrast ratings were conducted to address the short-term time frame of 5 years. That is, to determine if the proposed pipeline would achieve the requisite VRM class objectives within 5 years of construction. It is assumed that there would be substantially greater visual contrast introduced during construction, but that this would be acceptable as long as progress is made and the objectives are met within 5 years of construction.

Clarification for Section 3.8(1)(c)(i)(A)&(B)

DEQ Comment:

3.8(1)(c)(i)

Information and mapping based upon 1 or 2 dominant species and 1 or 2 understory species needs to be provided for the impact zones below.

(A) areas within 0.5 mile radius of pump or compressor stations

(B) crossing of streams with fishery value class of I or II or waterways with annual discharge of 1,000 cfs or more.

Keystone Response:

(A) Information and mapping of vegetation within a 0.5 mile buffer of the 12 potential pump station locations along the three proposed routes (A, A1A, and B) were developed following a three-step process.

1) Preliminary boundary delineation using aerial imagery.

2) Helicopter surveys for all three routes followed by ground verification efforts on selected PS sites, and

3) Final mapping.

The first step, preliminary desktop aerial interpretation, occurred during initial land use analysis and identified five plant community types (very low cover grasslands, low/moderate cover grassland, mixed riparian, wetlands and agricultural lands-dry crop) using digital aerial imagery (2006 NAIP 1-meter color imagery and 2005 DOQQ 1-meter color imagery).

Helicopter surveys were conducted in April 2009 for pump stations on all three route alternatives to assign vegetation/land use type. Furthermore, helicopter surveys were also conducted along the major river crossings (Milk River, Missouri River and Yellowstone River). In May 2009, field confirmation of selected sites was performed in order to field check types and develop species lists. Ground verification efforts identified the dominant plants within the upper and lower canopies of the vegetation profile within each plant community. Final mapping followed these efforts.

Very Low Cover and Low/Moderate Cover Grasslands

Within the very low cover and low/moderate cover grasslands graminoids were typically the dominant plants comprising the greatest canopy cover within the potential pump station locations. The dominant species in the very low cover grasslands type include blue grama (*Bouteloua gracilis*), Prairie June grass (*Koeleria macrantha*), western wheatgrass (*Pascopyrum smithii*), and threadleaf sedge (*Carex filifolia*). Associated species include clubmoss (*Saleginella densa*) and Hood's phlox (*Phlox hoodii*). The dominant species encountered within the low/moderate grasslands include western wheatgrass (*Pascopyrum smithii*), blue grama (*Bouteloua gracilis*), green needlegrass (*Nassella viridula*), and Idaho fescue (*Festuca idahoensis*). Other commonly dominant species encountered include Prairie June grass (*Koeleria macrantha*), Sandberg's bluegrass (*Poa secunda*), needle and thread grass (*Hesperostipa comata*), and threadleaf sedge (*Carex filifolia*). Shrub species such as *Symphoricarpos* spp. and *Artemisia frigida* and *Artemisia cana* were also encountered.

Keystone XL Project – Montana Major Facility Siting Act Application

Wetlands

The vegetation of the wetland community is characterized by a moderately dense to dense perennial graminoid layer dominated or codominated by *Carex nebrascensis*. Other graminoid species present are *Carex praegracilis*, *Calamagrostis stricta*, *Deschampsia caespitosa*, *Eleocharis palustris*, *Glyceria striata*, *Juncus balticus*, and *Schoenoplectus pungens*. This type is shown as emergent wetlands (PEM) or forested wetlands (PFO).

Mixed Riparian

Within the mixed riparian plant community the plains cottonwood (*Populus deltoides*) was the dominant overstory with the shrub species silver sage (*Artemisia cana*) and *Symphoricarpos* spp. occupying the understory. The herbaceous plant community includes the species bluejoint reedgrass (*Calamagrostis Canadensis*), Baltic rush (*Juncus balticus*), and sedges (*Carex* spp.).

Agricultural Lands–Dry Crop

Agricultural lands–dry crop plant community had crested wheatgrass (*Agropyron cristatum*) as the dominant plant species with smooth brome (*Bromus inermis*) also occurring. The agricultural lands-dry crop classification also includes dry-land wheat (*Triticum aestivum*) and other crops. These two types are broken into two classes in the tables below.

Agricultural Lands–Irrigated

Agricultural lands-irrigated is typically planted wheat.

Water

Waterbodies are one of three types: ephemeral (EPH), intermittent (INT), and perennial (PER). These are not shown in the vegetation tables below, but are displayed on the maps.

Developed Lands

Developed lands includes commercial (DCOM), residential (DRES), industrial (DIND) as well as right-of-way (DROW) designations. These are not shown in the vegetation tables below, but are displayed on the maps.

Clarification for Section 3.8(1)(c)(iii)(C)

DEQ Request:

3.8(1)(c)(iii)(C) for liquid pipelines, any additional waters where aquatic habitats could be adversely affected by a liquid spill or leak;

Keystone Response:

Attachment D, Section 3 estimates incident frequency conservatively as 1 release in any 1-mile segment every 7,500 years along the Project in Montana. A hypothetical release would have a 50 percent probability of being 3 barrels or less; 35 percent probability of being between 3 and 100 barrels; 10 percent probability of being between 100 and 1,000 barrels; 5 percent probability of being between 1,000 and 10,000 barrels; and a 0.5 percent probability of being more than 10,000 barrels. Please note that an amendment to Attachment D, Section 4 is also included in this submittal.

The method used to respond to Section 3.8(1)(c)(iii)(C) accounts for 100 percent of the alternative routes, and categorizes all portions of the pipeline that cross or are located near a National Hydrography Dataset (NHD)-defined waterway within one of the categories indicating where impacts might possibly occur. A 500 foot buffer along the pipeline on either side of waterways crossed was included as part of the crossing. All portions of the pipeline within ¼ mile of waterways were analyzed for surrounding topography. It was assumed that product could only travel over flat ground for 200 yards, or for up to ¼ mile over steep terrain with slopes greater than 5 percent. Buffers of ¼ mile were transposed on the routes, and slopes within the buffer were analyzed. Portions of pipeline in each simulated catchment within 200 yards, excluding areas with slopes greater than 5 percent, were identified as pipeline segments that could impact aquatic habitats (PSAH).

In order for impacts to occur, the following circumstances must all surround a release and happen at the same time and place: 1) be within a segment that could contribute to a stream; 2) be of a sufficient size to travel overland and reach the waterway; 3) have water flow in the waterway for transport; 4) have presence of aquatic habitat at or downstream from the introduction; and 5) have contaminant in a concentration (release size) great enough to impact the aquatic habitat. It is highly unlikely that all these circumstances would occur at the same time causing an impact to aquatic habitat. Mapbook 8 depicts the reaches of stream that might, although highly unlikely, have aquatic habitat impacted by a release. All these factors are shown in Table 1, which lists the length of each route's PSAH as an indication of the aquatic habitats that could be adversely impacted by a hypothetical release. All route alternatives have 1 percent or less contributing by direct flow to a perennial waterway. The postulated occurrence interval for theoretical impacts occurring in each category of PSAH along each alternative route is also noted by incident magnitude. Table 2 contains examples of calculations used to arrive at the occurrence intervals.

Keystone XL Project – Montana Major Facility Siting Act Application

Table 1 Categorization by Contribution Method of Pipeline Segments that Could Impact Aquatic Habitats

<u>Contribution Method</u>	<u>Miles of Route</u>	<u>Percent of Route</u>	<u>Potential Exposure of Aquatic Habitat - Occurrence Interval by Incident Size ¹ (years)</u>

<u>Direct flow to Perennial waterway</u>	<u>2.0</u>	<u>1%</u>	<u>7,519</u>	<u>10,741</u>	<u>37,594</u>	<u>75,188</u>
<u>Total</u>	<u>282.7</u>	<u>100%</u>	-	-	-	-

¹ Incident size: Very small=3 barrels; Small=50 barrels; Moderate=1,000 barrels; Large=10,000 barrels.

Occurrence interval calculations account for probability of each spill size (Att. D, Section 3.2), probability of flow in the waterway (Perennials flow 100%, Intermittent flow 50% of time), probability of resources being present (100% Perennial, 20% Intermittent have resources), and probability of spill size traveling overland to waterway (Very small = 5%, Small = 10%, Moderate = 30%, Large = 75%).

Table 2 Examples of Calculations of the Occurrence Intervals by Incident Size

<u>Very Small Size - Overland flow to Intermittent waterway</u>	One incident divided by the following denominator: Total miles (for Route A, 65.8 miles) * probability of a spill (0.000133 incidents/mile*year) * spill size's probability of occurring (very small, 0.5) * spill size's assumed probability of reaching the waterway via overland flow (very small, 0.05) * assumed probability of flow in the waterway (intermittent, 0.5) * assumed presence of a resource downstream in the waterway (intermittent, 0.2). <u>1 incident / (65.8 miles * 0.000133 incidents/mile/year * 0.5 * 0.05 * 0.5 * 0.2) = 45,707 years</u>
---	--

Keystone XL Project – Montana Major Facility Siting Act Application

Table 2 Examples of Calculations of the Occurrence Intervals by Incident Size

<u>Small Size</u> <u>Direct flow to Intermittent waterway</u>	One incident divided by the following denominator: Total miles (for Route A, 48.6 miles) * probability of a spill (0.000133 incidents/mile*year) * spill size's probability of occurring (small, 0.35) * assumed probability of flow in the waterway (intermittent, 0.5) * assumed presence of a resource downstream in the waterway (intermittent, 0.2). $1 \text{ incident} / (48.6 * 0.000133 \text{ incidents/mile/year} * 0.35 * 0.5 * 0.2) = 4,420 \text{ years}$
<u>Moderate Size</u> <u>Overland flow to Perennial waterway</u>	One incident divided by the following denominator: Total miles (for Route A, 1.3 miles) * probability of a spill (0.000133 incidents/mile*year) * spill size's probability of occurring (moderate, 0.1) * spill size's assumed probability of reaching the waterway via overland flow (moderate, 0.3) * assumed probability of flow in the waterway (perennial, 1.0) * assumed presence of a resource downstream in the waterway (perennial, 1.0). $1 \text{ incident} / (1.3 \text{ miles} * 0.000133 \text{ incidents/mile/year} * 0.1 * 0.5 * 1.0 * 1.0) = 192,790 \text{ years}$
<u>Large Size –</u> <u>Direct flow to Perennial waterway</u>	One incident divided by the following denominator: Total miles (for Route A, 0.8 miles) * probability of a spill (0.000133 incidents/mile*year) * spill size's probability of occurring (large, 0.05) * assumed probability of flow in the waterway (perennial, 1.0) * assumed presence of a resource downstream in the waterway (perennial, 1.0). $1 \text{ incident} / (0.8 \text{ miles} * 0.000133 \text{ incidents/mile/year} * 0.05 * 1.0 * 1.0) = 187,970 \text{ years}$

Attachment D, Section 4.2.2.4 discusses the potential impacts to aquatic habitats. **Tables 4-4 through 4-11 of Attachment D** contain details of potential impacts according to stream size and hypothetical release size. Please refer back to **Tables 1 and 2 in Attachment P** pages P-71 to P-81 for descriptions of aquatic habitat, special use sites, and fish distribution in perennial streams near the Keystone XL Project Alternatives.

Montana's Comprehensive Fish and Wildlife Conservation Strategy (MCFWCS) emphasized two aquatic focus areas within the project area, the Lower Missouri River and the Lower Yellowstone River. Portions of Routes A and A1A are in the Lower Missouri River area and a portion of Route B is within the Lower Yellowstone River area. These prairie stream drainages include large perennial warmwater rivers, breaks and coulees, pothole lakes, and intermittent streams (MCFWCS 2005). There are a total of 55 aquatic (2 crayfish, 3 mussel, and 50 fish) species that are found within the Lower Missouri River Focus area and 65 aquatic (1 crayfish, 3 mussel, and 60 fish) species within the Lower Yellowstone River Focus Area (MCFWCS 2005). After meetings between Keystone representatives and Montana Fish, Wildlife, and Parks (MFWP) in 2008 and 2009, the northern redbelly dace x finescale dace and pearl dace were the only species of concern that have the potential to occur within intermittent streams with suitable habitat crossed by the Project.

Conclusion

This conservative analysis of the proposed Project alternatives coupled with the Keystone XL Project Pipeline Risk Assessment and Environmental Consequence Analysis for Montana (Attachment D) demonstrates that the predicted frequency of incidents is very low, the probability of a large spill occurring is very low, and, consequently risk of a release that would impact aquatic habitats is extremely low. Compliance with regulations, application of Keystone's IMPs and Emergency Response Plan (ERP), as well as adherence to safety procedures will help to ensure long-term, environmentally sound, and safe operation of the pipeline.

Clarification for Section 3.8(1)(c)(iv)

DEQ Request:

3.8(1)(c)(iv) for a liquid pipelines facility, a detailed assessment of the consequences of a spill or leak downstream of each crossing of a perennial waterway, including a description of the principal resources that would be affected, the magnitude of the impact to fishery resources and habitat, and a description of proposed spill detection, containment, and cleanup techniques;

Keystone Response:

Table 1 below indicates perennial waterway crossings for each route and the associated resources that could be impacted by a hypothetical release at each crossing along with shading that indicates the magnitude of impacts that might be expected from a hypothetical release. Resources were identified through multiple sources. Fisheries that are downstream of potential hypothetical releases at perennial waterway crossings are the same as those listed in **Attachment P**, pages P-71 to P-81. Public water supply system intakes were identified through data from MDEQ (MDEQ 2009). USGS 24K topographic maps were also utilized in the analysis of resources.

Table 2 below lists streamflow statistics for perennial streams crossed by the alternative routes where gaging station records were available. These perennial streams can be classified according to their average annual flow by the stream categories within Table 4-1 in the Project Pipeline Risk Assessment and Environmental Consequences Analysis for Montana (**Attachment D**).

Attachment D, Section 4.2.2.4 provides information regarding the magnitude of possible impacts to aquatic ecosystems. The magnitude of effects varies with multiple factors, the most significant of which include the amount of material released, the size of the spill dispersal area, the type of crude oil spilled, the species assemblage present, climate, and the spill response tactics employed. If a hypothetical release were to occur along a PSAH to the streams and rivers referenced in **Table 2**, the magnitude of the impacts can be estimated to those specific streams by referencing the average annual flow at the gage (after considering any necessary adjustment for tributaries and/or distance from gage to crossing) to **Attachment D**, Section 4.2.2.4.

Hypothetical release frequency and size is discussed in Chapter 1, Section 1.5.5 of the MFSA application on page 1-34. Hypothetical release detection is described in Chapter 1, Section 1.5.6 on pages 1-34 and 1-35.

Containment and cleanup will be addressed in the Spill Prevention, Control and Countermeasure (SPCC) Plan for construction and in the Emergency Response Plan (ERP) for operations. A draft SPCC Plan was provided in the April 7, 2009 (green) supplemental filing. An outline of the ERP can be found in **Attachment B**. The Keystone XL ERP, which is based on the previously PHMSA- approved Keystone ERP, is under development and will be filed with PHMSA for review prior to operations.

Conclusion

This conservative analysis of the proposed Project alternatives coupled with the Keystone XL Project Pipeline Risk Assessment and Environmental Consequence Analysis for Montana (**Attachment D**) demonstrates that the predicted frequency of incidents is very low, the probability of a large spill occurring is very low, and, consequently, risk of a release that would impact principal resources or fishery resources and habitats is minimal. Compliance with regulations, application of Keystone's Integrity Management Program and ERP, as well as adherence to safety procedures will help to ensure long-term, environmentally sound, and safe operation of the pipeline.

¹ Based on average annual stream flow after considering any necessary adjustment for tributaries and/or distance from gage to crossing where appropriate, or on stream width when no gage data was available.

² Incident size: Very small=3 barrels; Small=50 barrels; Moderate=1,000 barrels; Large=10,000 barrels.

Shading indicates concentrations that could potentially cause acute toxicity to aquatic species according to Attachment D, Table 4-7. The darkest shading represents high probability of acute toxicity (>10 times the toxicity threshold), lighter shading represents moderate probability of acute toxicity (1 to 10 times the toxicity threshold), and unshaded areas represent low probability of acute toxicity (< toxicity threshold).

Occurrence interval based on the conservative overall predicted incident frequency of 0. 000133 incidents/mile*year, projected frequencies of each spill volume (Attachment D, Section 3.2), and calculated with miles of CPS per crossing prior to rounding.

Clarification for Section 3.8(1)(c)(v)

DEQ Request:

3.8(1)(c)(v) for any wetlands or other waterfowl habitat downstream from a river crossing that could be adversely affected by a liquid spill or leak, information on seasonal abundance and species composition of waterfowl populations.

Keystone Response:

Wetlands that have the possibility of being affected by a hypothetical release were identified through GIS analysis of the National Land Cover Dataset (NLCD) 2001. Any areas attributed in the NLCD as wetland land cover was considered; "Emergent Herbaceous Wetlands" and "Woody Wetlands" were both present in the area. Any wetlands over 1 acre surface area and intersecting with the hypothetical release paths, along with additional wetlands identified along possibly affected reaches of the Yellowstone and Missouri rivers were categorized and presented to the MFWP in May 2009 for information on waterfowl species composition and seasonal abundance. Based on the response from MFWP, these data are not available and to provide these data, surveys would need to be conducted during three seasons. MFWP advised that specific data on such waterfowl species and seasonal abundance is not available. General information that is available is provided in the discussion below. Based on this discussion, this item should be deemed complete.

Source: USGS. 2001. National Land Cover Database (NLCD) 2001

The Project is located within the Central Flyway for migrating bird species. Medicine Lake National Wildlife Refuge (NWR), located along and adjacent to routes A and A1A, provides representative information for the seasonal abundance and composition of waterfowl within the Project area. Medicine Lake NWR has long been recognized for its importance to breeding and migrating waterfowl and was the primary reason for the purchase of the refuge in 1935 (USFWS 2009). Most common nesting ducks are mallard, gadwall, northern pintail, northern shoveler, blue-winged teal, and lesser scaup, with a total of 14 species breeding locally (USFWS 2009). More than 300 pairs of Plains Canada geese breed in the refuge complex (USFWS 2009). Spring and fall migrations bring thousands of waterfowl to the refuge, mostly ducks, Canada and white-fronted geese, and tundra swans, with a smaller number of snow geese (USFWS 2009).

Clarification for Section 17.20.815(6)

DEQ Request:

Design capacity and operational characteristics.

Describe design capacity and operational characteristics for associated facilities.

Keystone Response:

The proposed service to Project pump stations are 115 kilovolt (kV) transmission lines, with a proposed transmission structure matching the TP-115; a single pole, horizontal post insulator design.

Three factors are considered in designing a power line. The first is the voltage characteristic during load flow, or voltage drop. This is a combination of the load current and the resistance of the conductor. Though the final conductor size has not been determined for Project power lines, the conductor will have a minimum ampacity of 560 amps. Using that, the maximum load at 115 kilovolts would be 110 megawatts. For all locations, source voltage is the determining factor in the circuits to be used, not load flow. For example, initial load flow calculations indicate the 115 kV circuit will be needed to maintain the voltage regulation (spread between no-load and loaded circuit voltage) to select Project pump stations. Using this voltage will be more economical rather than adding transformation costs.

The second factor is the power limit of the line. Bulletin 62-5 “Electrical Characteristics of AC Transmission Line Designs” (USDA 1976) outlines a parameter called Surge Impedance Loading, or SIL. The published SIL value for the TP-115 structure proposed for the Project is 36 megawatts (MW), which is the optimum load for a line of this design with a distance equal to 300 miles. A line shorter than 300 miles can be loaded more heavily than 36 MW, and a longer line should be loaded less than that. The longest proposed power line within Montana is approximately 50 miles in length. The published SIL would indicate that a 115 kV line would be able to very capably serve the 25 MW Project loads.

Theoretically, the stability (or power) limit for a transmission line is calculated using the following equation:

$$\text{Power Max} = (0.75 * \text{Voltage (in kilovolts)}^2) / \text{line length (in miles)}$$

For a 115 kV circuit, 50 miles in length, that maximum power would be:

- $P_{\text{max}} = (.75 * 115^2) / 50$
- $P_{\text{max}} = 9920 / 50$
- $P_{\text{max}} = 198 \text{ megawatts.}$

Based on the above formulas, the optimum load for the proposed 115 kV lines lies between 36 and 200 MW, depending upon the conductor size chosen. The distances for each of the proposed transmission lines are known factors. Therefore, the conductor size will vary. Based on current estimates, the minimum conductor size will be at least 397 aluminum conductor steel reinforced (ACSR) or larger.

The third factor considered is limitation of motor starting, or flicker, seen by other users of the circuits interconnecting to the power lines for Project pump stations. The current is lower for the 115 kV line, in comparison to a lower voltage circuit. This assists in mitigation of any flicker or disturbance to the line with motor starting. Thus, the 115 kV rating is desirable for these loads, especially if other customers are fed from the same circuit.

Clarification to 75.20.1511(9)

(9) Construction camps

DEQ Comment:

Update requested. Keystone has recently indicated that worked camps are being planned in the areas of Nashua and Baker, Montana. To address this rule, please provide a description of the camps planned for the construction crew, and how they will be operated.

Keystone Response:

Based on an in-depth housing analysis and on updated discussions with construction contractors, Keystone plans to use temporary construction camps. These temporary camps will supplement local housing in remote areas of Montana for the duration of construction in the area. Currently, Keystone is considering two camps in Montana, generally situated at the spread breaks between Spreads 1 and 2 and between Spreads 3 and 4.

Each camp will be designed to house approximately 600 people. Camps will consist of prefabricated, modular, dormitory-style units that include heat and air conditioning systems. Camps typically will include sleeping areas with shared and private baths, craft rooms, recreation facilities, telecommunication/media rooms, kitchen/dining facilities, laundry facilities, security/infirmity unit, offices, and wastewater treatment facilities.

Construction camp sites will be approximately 80 acres each in size, of which 30 acres will be used as a contractor yard and 50 acres will be used as the actual camp site. Within the acreage designated for the camp site, space will also be set aside for RVs. The water, electricity, and wastewater for RVs will be tied into one camp system. Camps will be permitted, constructed, and operated in compliance with applicable county, state, and federal regulations. **Table 1** summarizes the regulations and permits required for construction camps based upon preliminary designs of the camps. Final design will be accomplished after bidding and hiring contractors to build and maintain the camps. Keystone will be responsible for obtaining all permits. Due to the timing of engaging a contractor to build and operate the camps, Keystone will acquire permits based upon a preliminary design for each camp.

Where feasible, potable water will be provided by drilling a well. If an adequate water supply cannot be obtained from the well, water will be provided by municipal sources or trucked to each camp. A wastewater treatment facility will be included in each camp to treat wastewater to meet regulatory standards prior to discharge.

In areas where construction camps are used, camps will include a health, safety and environment program, fire and HAZMAT protection programs (NFPA Level 101), and a vector program. Therefore, strains on the public services in areas where camps are employed would be minimal.

Keystone XL Project – Montana Major Facility Siting Act Application

Table 1 Construction Camp Permits and Regulations

<u>Agency/State</u>	<u>Permit/Discussion</u>
<u>Montana</u>	
<u>Montana DEQ</u>	<u>Public water and sewer (PWS) laws, Title 75, chapter 6, part 1, MCA. Rules at Administrative Rules of Montana (ARM) 17.38 101, and Department Circulars incorporated by reference. Require plan and spec review before construction of a public water or sewer system. Circulars contain design requirements. Requires water quality monitoring of water supply.</u> <u>Sanitation in subdivisions laws, Title 76, Chapter 4, MCA. Rules at ARM Title 17, Chapter 36. If applicable, requirements would be the same as the PWS laws and Circulars for water supply and wastewater. Would require additional review of stormwater systems and solid waste management. (Likely not applicable unless created "permanent" multiple spaces for mobile homes or RVs. 76-4-102(16), MCA.)</u> <u>Water Quality Act Discharge Permits, Title 75, Chapter 5, MCA. Rules at ARM Title 17, Chapter 30. Groundwater discharge permit would be required if a wastewater drain field had a design capacity over 5,000 gpd. ARM 17.30.1022.</u> <u>Air permit for diesel fired generators.</u>
<u>Department of Public Health and Human Services (DPHHS)</u>	<u>Work Camp licensing laws, Title 50, Chapter 52, MCA. Rules at ARM Title 37, Chapter 111, Subchapter 6. Regulations regarding water, sewer, solid waste, and food service. Incorporates DEQ PWS requirements but has additional water and sewer provisions. Administered by DPHHS, Public Health and Safety Division, Communicable Disease Control and Prevention Bureau, Food and Consumer Safety Section.</u>
<u>Counties</u>	<u>Permit required for wastewater systems, Regulations adopted under Section 50-2-116(1)(k), MCA. Adopting state minimum standards promulgated by Board of Environmental Review at ARM Title 17, chapter 36, Subchapter 9. Generally follow state laws for subdivisions, PWS, DEQ-4.</u> <u>Work camp permit required in some counties.</u>

The Project is in the process of identifying existing electric power infrastructure to supply power to each of the construction camps. However, if existing infrastructure is not available, diesel-fired internal combustion engines may be used to supply primary power to one or more of the construction camps. Additionally, even if power line infrastructure to each of the construction camps is available, the Project may install diesel-fired internal combustion engines as emergency back-up generators, to supply power to the camps if electrical power from the local utility is interrupted. To determine preliminary emissions estimates from the diesel-fired generator engines, a worst-case scenario of four, 400-kilowatt generator engines was assumed for installation per camp. This worst-case scenario would occur if electrical power to one of the construction camps was unavailable. Each of the diesel-fired engines would be "Tier 3" certified engines and are assumed to operate 8,760 hours per year. Preliminary estimates of emissions associated with four primary power generators are

Keystone XL Project – Montana Major Facility Siting Act Application

included in [Table 2](#) and preliminary estimates of emissions from one backup generator are included in [Table 3](#).

<u>SO_x</u>	<u>0.054</u>	<u>lb/MMBtu</u>	<u>0.25</u>	<u>1.08</u>
<u>Pb</u>	<u>9.0</u>	<u>lb/10¹² BTU</u>	<u>4.1E-05</u>	<u>1.8E-04</u>

The Project also will be subject to air quality regulatory programs in Montana if generator engines are needed to supply power at one or more of the construction camps.

New Source Performance Standard regulations establish a standard of performance for new, modified, or reconstructed sources, which fall into any specified source category, regardless of geographic location or the existing ambient air quality. The standards define emission limitations for a particular source group. The NSPS potentially applicable to the Project, which may apply to the construction camp generator engines, include Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines, as discussed below.

Subpart IIII – Standards of Performance for Stationary Compression Ignition Internal Combustion Engines

In 2006, USEPA promulgated this rule that applies to stationary diesel-fired internal combustion (IC) engines and that sets standards for oxides of nitrogen (NO_x), CO, PM, and non-methane hydrocarbon (NMHC), along with limiting SO₂ emissions through use of lower sulfur fuel. This regulation may apply to the generator engines at the construction camps, depending upon the manufacture dates of the engines. The primary burden of the proposed regulation falls on IC engine manufacturers, rather than on owners/operators, since engine manufacturers must certify their engines to the emission standards.

The ARM, Title 17, lays the framework for the state air quality laws and regulations in Montana. The ARM establishes the legal authority of the MDEQ to enforce the regulations set forth by the Clean Air Act of Montana, Title 75. Chapter 8 of Title 17 of the ARM identifies the air quality regulations that would apply to the generators at the construction camps, if the generators are installed. Specifically, Subchapter 7 includes provisions for the construction and operating permit requirements of air contaminant sources. These regulations would apply if the construction camp generators are installed at construction camps in Montana.

Keystone XL Project – Montana Major Facility Siting Act Application

The diesel-fired generator engines that may be located at one or more of the construction camps in Montana if line power is not acquired will have criteria pollutant emission levels below 100 tpy. Therefore, the construction camps would not be subject to Title V operating permit requirements. However, if the generator engines are located at the construction camps long enough for them to be considered stationary sources, they would be subject to state minor source air permitting requirements. The diesel-fired engines may be subject to Subpart IIII of the NSPS, if the engines are manufactured after the regulatory applicability date as specified in the regulation for that engine power rating. The construction camps will comply with Montana air quality permitting requirements if it is determined that installation of the generator engines at one or more locations is required.

Wastewater will be treated with a system established on the site to handle the anticipated volume of wastewater discharge from the camp and to meet the effluent standards required in each county where the camps are located. The details of the wastewater treatment facilities will be provided once a contractor has been selected.

The camp will require approximately 45,000 gallons of water per day. If water wells cannot be installed or can not provide this volume of water, Keystone will look to nearby municipal systems and purchase the water required.

Clarification for Section 17.20.1512(7)(a-g)

DEQ Request:

7) Detailed Spill Contingency Plan

- a. Immediate Notification Procedures
- b. Type and Location of Emergency Response Personnel and Equipment
- c. Any Mutual Aid Agreements to supply Personnel and Equipment and Respond in the Event of a Spill
- d. Response Procedures
- e. Equipment Testing Procedures
- f. Frequency of Field Training Exercises
- g. Plan Update Procedures

Keystone Response:

7) Detailed Spill Contingency Plan

As an interstate liquids pipeline, Keystone is required by federal regulation to develop a detailed Emergency Response Plan (ERP or Plan) prior to commencing pipeline operations. The Plan must be filed for review with the US Department of Transportation (US DOT), Pipeline and Hazardous Materials Safety Administration (PHMSA). Keystone developed an ERP for the initial Keystone Pipeline project. That ERP was approved by PHMSA in January 2009. Keystone is now in the process of preparing an ERP specifically for the Keystone XL Pipeline. The Keystone XL ERP will utilize the work done on the Keystone ERP to the extent applicable. The Keystone XL ERP also will be customized to include numerous location- and project-specific elements. The Keystone XL ERP will be filed with PHMSA prior to commencing operations. The ERP cannot be filed until such time as final pipeline design is completed and route approvals received so that site specific information can be developed for incorporation into the Plan. Keystone will liaise with state and local officials to ensure coordination with local and state offices of disaster services as the Plan is further developed.

The Keystone XL Project ERP will have five broad components: the Plan itself; resources (equipment, personnel, and contractors); training; continuous improvement; and public awareness. Each component is integral to the build up and success of the program and needs to proceed collectively once implemented.

The overall strategy behind the ERP is to manage risks and be able to address the potential consequences in the event of a release. The ERP needs to satisfy regulatory requirements and be user friendly and practical for operations. The ERP must be understood and implemented by field operations which will be achieved through training programs.

Emergency management will be built into pipeline operations through a series of training exercises that direct operations to test and maintain the ERP on an on-going basis.

The Plan is being developed using proprietary software called “ePlan”. This will mean that the entire Plan will be electronic and revised on a continual basis making the Plan current all the time. Administratively, the Plan will be part of the corporate Emergency Management System.

Keystone XL Project – Montana Major Facility Siting Act Application

The Plan will include Response Zones, notifications, public official listings, contractors, technical response procedures, forms, and other elements.

a. Immediate Notification Procedures

Keystone is required by law to notify immediately the National Response Center (NRC) if an event: (1) violates water quality standards; (2) creates a sheen on water; or (3) causes a sludge or emulsion to be deposited beneath the surface of the water or upon adjoining shorelines (40 CFR Part 112). In addition to the NRC notification, Keystone will make timely notifications to other agencies, including the appropriate local emergency planning committee, sheriff's department, US Environmental Protection Agency (USEPA), and affected landowners.

b. Type and Location of Emergency Response Personnel and Equipment

The specific locations of Keystone's emergency responders and equipment will be determined upon conclusion of the pipeline detailed design and the completion of Keystone's ERP. Keystone will base Company emergency responders consistent with industry practice and in compliance with the applicable regulations, including 49 CFR Parts 194 and 195. Keystone's response time to transfer additional resources to a potential leak site will follow an escalating tier system, with Keystone's initial emergency responders capable of reaching all locations within Montana within 6 hours in the event of a spill. Typically, emergency responders will be based in closer proximity to the following areas:

- Commercially navigable waterways and other water crossings.
- Populated and urbanized areas, and
- Unusually sensitive areas, including drinking water locations, ecological, historical, and archaeological resources.

Consistent with industry practice and in compliance with applicable regulations, the types and amount of emergency response equipment based on worst case discharge volumes that will be pre-positioned for access by Keystone will be determined upon conclusion of the pipeline detailed design and the completion of Keystone's ERP, but prior to commencing line fill.

Emergency response equipment will be strategically situated along the pipeline route. Types of emergency response equipment are detailed below. Keystone will engage a national response contractor who will have access to and be able to provide large quantities of equipment to meet Oil Spill Response Organization (OSRO) requirements. Keystone also will have a number of local contractors available to provide emergency response assistance as required. Finally, Keystone will have a contract Spill Management Team available to respond and assist with incident management in the event of a significant release.

The overall strategy is to purchase and situate enough equipment for a Tier 1 response in each Response Zone. A Tier 1 response means a company leak that can be contained, controlled, and cleaned up using primarily Company personnel within a defined period of time from when a release is discovered, which, according to US Department of Transportation (US DOT) regulations, is 6 to 12 hours, depending on the location. It is important to note that the tiered level of response pertains to time requirements and is completely independent of spill threshold volumes. Although volumes are important for determining the correct amount of equipment needed for the tiered response times, they are not intended to define a spill threshold amount. It is well understood by the US DOT/PHMSA that once a Tier 1 requirement is satisfied, Keystone will cascade equipment to Tiers 2 and 3 until enough equipment is available to respond to the Worst Case Discharge amount.

The equipment will be stored strategically along the pipeline typically in the center of the Response Zone and accessible by Keystone and contract staff.

Keystone XL Project – Montana Major Facility Siting Act Application

Consistent with industry practice and in compliance with the applicable regulations, including 49 CFR Parts 194 and 195, the types of emergency response equipment that will be pre-positioned for access by Keystone are highlighted below:

- Pick-up trucks, one-ton trucks and vans;
- Vacuum trucks;
- Work and safety boats;
- Containment boom;
- Skimmers;
- Pumps, hoses, fittings and valves;
- Generators and extension cords;
- Air compressors;
- Floodlights;
- Communications equipment including cell phones, two way radios and satellite phones;
- Containment tanks and rubber bladders;
- Expendable supplies including absorbent booms and pads;
- Assorted hand and power tools including shovels, manure forks, sledge hammers, rakes, hand saws, wire cutters, cable cutters, bolt cutters, pliers and chain saws;
- Ropes, chains, screw anchors, clevis and other boom connection devices;
- Personnel Protective Equipment (PPE) including rubber gloves, chest and hip waders and H₂S, O₂, LEL and benzene detection equipment; and
- Wind socks, signage, air horns, flashlights, megaphones and fluorescent safety vests.

Additional equipment including helicopters, fixed wing aircraft, all-terrain vehicles (ATV's), snowmobiles, backhoes, dump trucks, watercraft, bull dozers, and front-end loaders may also be accessed depending upon site-specific circumstances. Other types, numbers and locations of equipment will be determined upon conclusion of the pipeline detailed design and the completion of Keystone's ERP.

c. Any Mutual Aid Agreements to Supply Personnel and Equipment and Respond in the Event of a Spill

Keystone will investigate opportunities to form and participate in mutual aid agreements once the pipeline begins operations.

d. Response Procedures

SCADA System

Keystone will be operated from an Operations Control Center (OCC), which will be manned on a 24 (hrs/day) x 7(days/week) basis. Keystone will utilize a Supervisory Control and Data Acquisition (SCADA) system to remotely monitor and control the pipeline system. Keystone's SCADA system will include:

- Redundant fully functional backup OCC available for service at all times;
- Automatic features installed as integral components within the SCADA system to ensure operation within prescribed pressure limits; and
- Additional automatic features installed at the local pump station level also will be utilized to provide pipeline pressure protection in the event communications with the SCADA host are interrupted.

Leak Detection Systems

Keystone will have a number of complimentary leak detection methods and systems available within the OCC. These methods and systems are overlapping in nature and progress in leak detection thresholds.

- The first leak detection method is remote monitoring performed by the OCC Operator. Remote monitoring consists primarily of pressure and flow data received from pump stations and valve sites fed back to the OCC to detect leaks down to approximately 25 percent – 30 percent of pipeline flow rate.
- Next are software based volume balance systems that monitor injection and delivery volumes. These systems are typically able to detect leaks down to approximately 5 percent of pipeline flow rate.
- Next are Computational Pipeline Monitoring or model based leak detection systems that break the pipeline system into smaller segments and monitor each of these segments on a mass balance basis. These systems compensate for line pack and are typically capable of detecting leaks down to a level approximately 1.5 percent to 2 percent of pipeline flow rate.
- Finally, we will use direct observation methodologies, which include aerial patrols, ground patrols and public and landowner awareness programs that are designed to encourage and facilitate the reporting of suspected leaks and events that may suggest a threat to the integrity of the pipeline.

Emergency Response

In the event Keystone suspects a leak or a leak is reported to the OCC, Keystone would respond with an emergency pipeline shutdown. This would involve stopping all operating pumping units at all pump stations. Depending on the flow rate at the time of the incident this would mean stopping two to three pumping units at each of Keystone's 39 pumping stations in the US and Canada. This line shutdown is estimated to take approximately 9 minutes. Once all the operating pumping units have been shut down, the OCC Operator would close the sectionalizing or isolation valves in the vicinity of the leak to limit any further draindown at the leak site. Closure of these isolation valves would take an additional 3 minutes. Therefore, from when the leak was reported or alarm received, it would take approximately 12 minutes to shut down and isolate the pipeline. For purposes of estimating worst case spill volumes, however, Keystone has assumed an additional 10 minute period, which is the maximum period an operator is allotted to verify the condition and begin to shut down the affected segment of pipe.

The on-call response designate will be required to respond to and verify an incident. Once the OCC notifies the individual and an assessment of the probability and risk is established, field personnel may elect to dispatch other resources as soon as practical. It is recommended that each truck contain the basic oil spill response equipment such as absorbent boom, rakes, shovels, safety equipment, road barricades etc. The exact first responder equipment strategy is in the developmental stage.

It is anticipated that once the call is received, on-call personnel should respond and arrive on-site within 4 hours. Keystone is required by 49 CFR Part 194 to calculate Worst Case Discharge and address response and mitigative measures within each Response Zone.

Keystone will use environmental information collected during the application process and incorporate response and mitigative measures in the ERP. In addition, an aerial reconnaissance of the route will be completed to verify this information and develop site-specific Tactical Plans for those areas requiring additional details pertaining to an emergency event.

One of the most critical aspects of an emergency is communication and site management. While Keystone will send first responders and verifiers to the site, a mobile command post is recommended to act as a communication link between the site and the Emergency Operations Center. It is envisioned that this will be handled by an outside contractor that can arrive on-site within 12 hours. We have included a very small office inside the 34 foot trailers which would include basic communication equipment including satellite phones.

Keystone XL Project – Montana Major Facility Siting Act Application

Keystone will maintain personnel on-call on a 24(hrs/day) x 7(days/week) basis. These first responders will consist of both employees and contract personnel and will be based at various locations along the length of the pipeline.

The number of emergency responders comprising specific response teams will be determined upon completion of Keystone's ERP. Emergency responders will meet or exceed the requirements of 49 CFR Part 194.115.

Typically, emergency response teams would be comprised of Hazardous Waste Operations and Emergency Response (HAZWOPER) trained personnel as follows:

Tier 1: 8 HAZWOPER trained personnel (includes Emergency Site Manager and Command Post Safety Officer).

Tier 2: 12 HAZWOPER trained personnel.

Tier 3: 24 HAZWOPER trained personnel.

Responders will be dispatched from multiple locations and will have access to alternative means of transportation if weather or other conditions limit access. Alternative means of transportation will include fixed wing aircraft, helicopter, boats and other watercraft, all terrain vehicles, and snowmobiles.

Following execution of the emergency pipeline shutdown, the OCC operator will perform internal notifications as described in the ERP and dispatch first responders to the location identified. Key individuals would then be notified and Keystone's ERP activated as follows:

First Responder

- Notification of potential spill and dispatch received from OCC;
- Spill verified;
- Notification of Emergency Services, if required; and
- Verify with OCC:
 - Pipeline shutdown and status;
 - Pipeline segment isolation; and
- Regional EOC Manager and Qualified Individual (QI) notified.

Regional EOC Manager (QI)

- Notification received from OCC;
- Notification of spill details received from First Responder;
- Oil spill response plan activated;
- Emergency Site Manager (QI) notified;
- Regional EOC activated
- Mobilize response resources requested by Emergency Site Manager (QI);
- Corporate EOC Manager contacted; and
- Agency contacts including the National Response Center and other state and local agencies contacted.

Keystone XL Project – Montana Major Facility Siting Act Application

Incident Commander

- Notification received from Regional EOC Manager (QI);
- On-site First Responder contacted to obtain briefing on spill;
- On-site Command Post activated;
- Regional EOC advised of resource requirements; and
- First Responder relieved.

Response efforts are first directed to preventing or limiting any further contamination of the waterway, once any concerns with respect to health and safety of the responders have been addressed. This is typically accomplished primarily with containment booms and berms. The Incident Commander assumes responsibility for selecting the appropriate locations for construction of berms and deployment of booms as well as communicating any additional resource requirements to the EOC Manager.

Efforts are initially directed toward containing any spilled product on land prior to it reaching the waterway. With the approval of authorities having jurisdiction, activities such as digging ditches and building berms would be undertaken on the down slope of the spill site, to prevent any overland flow of spilled product from entering the waterway. In some cases it may be possible to use a combination of ditches and berms to divert the overland flow of spilled product to a collection point.

To contain the spilled product once it has reached the waterway, efforts are typically directed toward the deployment of containment boom as close as practical and safe downstream of the spill location. With the approval of the authorities having jurisdiction, the Incident Commander assumes responsibility and a tactical plan is developed for selecting a suitable location for the deployment of containment booms, based upon the waterway site-specific conditions, including flow velocity and avoidance of rapids and falls to ensure the effectiveness of the containment booms.

Product is typically recovered from the surface of water and transferred to containment facilities by a combination of mechanical skimming, vacuum recovery, and sorbent materials. Typical methods for the recovery and transfer to containment facilities for product spilled on land include vacuum recovery and sorbent materials.

The cleaning of shorelines and other affected natural or manmade structures is typically performed by traditional methods including wiping, hot water and low or high pressure wash down and the use of surfactants and emulsifiers or other agents. Water and other liquids used for wash down purposes for onshore applications are typically contained and collected using a combination of ditches and berms as described above. All site-specific cleaning methods and materials to be utilized are subject to the approval of the authorities having jurisdiction.

Product laden soils are typically either removed or treated with bioremediation in the event such intrusive cleanup techniques are not appropriate. These and other methods of cleanup including natural recovery, burning, dispersants, and other chemical usage can be considered in accordance with and at the discretion of the authorities having

Consistent with industry practice and in accordance with regulations including 49 CFR Part 194.115, Keystone's response time to transfer such additional resources to a potential leak site will follow an escalating or tier system. Dependant upon the nature of site specific conditions and resource requirements, Keystone will meet or exceed the following requirements, along the entire length of the pipeline system:

Keystone XL Project – Montana Major Facility Siting Act Application

<u>49 CFR Part 194</u>	<u>Tier 1 Resources</u>	<u>Tier 2 Resources</u>	<u>Tier 3 Resources</u>
<u>High volume area¹</u>	<u>6 hours</u>	<u>30 hours</u>	<u>54 hours</u>
<u>All other areas</u>	<u>12 hours</u>	<u>36 hours</u>	<u>60 hours</u>

¹ High volume area means an area with an oil pipeline having a nominal outside diameter of 20 inches or more, crosses a major river or other navigable waters, which, because of the velocity of the river flow and vessel traffic on the river, would require a more rapid response in the case of a worst-case discharge or the substantial threat of such a discharge.

Tier 1, 2, and 3 resources will typically include equipment as described above, along with additional HAZWOPER trained response personnel, as required to effectively respond to site specific conditions and as directed by the Incident Commander.

The primary task of the Tier 1 response team is to minimize the spread of product on the ground surface or water in order to protect the public and unusually sensitive areas, including ecological, historical, and archaeological resources and drinking water locations. The Incident Commander will make an assessment of the site-specific conditions, such as:

- The nature of the spilled product;
- Source of the spill;
- Direction(s) of spill migration;
- Known or apparent impact of subsurface geophysical feature that may be affected;
- Overhead and buried utility lines, pipelines, etc.;
- Nearby population, property or environmental feature that may be affected; and
- Concentration of wildlife and breeding areas.

The Incident Commander will request additional resources in terms of personnel, equipment and materials, from the Tier 2 and, if necessary, the Tier 3 response teams. Once containment activities have been successfully concluded efforts are directed toward the recovery and transfer of free product. Site cleanup and restoration activities follow, all of which are conducted in accordance with the authorities having jurisdiction.

Keystone will utilize both employees and contractors as emergency responders within its initial response efforts in the event of a pipeline spill. In the case of contractors and other spill response organizations, Keystone will have agreements in place identifying and ensuring the availability of the specified personnel, consistent with industry practice and in compliance with the applicable regulations, including 49 CFR Parts 194 and 195.

e. Equipment Testing Procedures

Emergency response equipment will be maintained and tested in accordance with manufacturers recommendations. Problems and deficiencies will be immediately corrected.

Keystone XL Project – Montana Major Facility Siting Act Application

f. Frequency of Field Training Exercises

Emergency Response Program training will include a combination of regulatory compliance and technical training. To achieve regulatory compliance, Keystone will ensure its employees have all mandatory training, including becoming Qualified Individuals and HAZWOPER compliant. Other regulatory requirements will be included in a regular training schedule for operations personnel.

From a technical training perspective, field technicians and managers will be participating in water-based spill response scenarios on an annual basis. Other training elements will be documented in the ERP and be implemented according to the prescribed regulatory agenda. Emergency response agencies and public officials will be invited to observe the field exercises. Staff also will be trained on Incident Command System levels 100/200 and some key staff also will be trained in ICS 300. The Incident Command System is a prescriptive system of responding and managing incidents. Technical staff will be completing ICS 100/200, while management will be completing ICS 300. Training includes class room lectures, table top exercises, on-call drills, field deployment on both land and water, and mutual aid participation.

It is recommended that each region complete at least five exercises per response zone annually. These include a water based drill, table top exercises, dry land deployments, attendance at mutual aid events, etc.

The positions and training requirement for on-site personnel have been identified as follows:

<u>Position</u>	<u>Specialized Training to Meet Oil Spill Response Duties</u>
<u>First Responders</u>	<u>Hazardous Waste Operations and Emergency Response (HAZWOPER) training to Hazmat Technician Level 3 with annual refresher, as required</u> <u>Keystone Emergency Management System (EMS) training</u> <u>National Fire Protection Association (NFPA) training</u>
<u>Emergency Site Manager – Qualified Individual</u>	<u>HAZWOPER training to Hazmat Level 4 Specialist with annual refresher, as required</u> <u>ICS Communication training</u> <u>Keystone EMS training</u> <u>NFPA training</u>
<u>Command Post Media</u>	<u>Keystone EMS training</u> <u>Keystone Media Relations training</u>
<u>Command Post Safety</u>	<u>Keystone EMS training</u> <u>Advanced safety related training</u>
<u>Command Post Documentation</u>	<u>Keystone EMS training</u>
<u>Command Post Site Security</u>	<u>Keystone EMS training</u>
<u>Command Post Resource Mobilization</u>	<u>Keystone EMS training</u>
<u>Command Post Technical</u>	<u>Keystone EMS training</u>
<u>Command Post Staging Leader</u>	<u>Keystone EMS training</u>
<u>Regional EOC Resource Mobilization</u>	<u>Keystone EMS training</u>

Keystone XL Project – Montana Major Facility Siting Act Application

<u>Position</u>	<u>Specialized Training to Meet Oil Spill Response Duties</u>
<u>Regional EOC Community Evacuation Leader</u>	<u>Keystone EMS training</u>
<u>Regional EOC Administration Support</u>	<u>Keystone EMS training</u>

g. Plan Update Procedures

The Plan is being developed using proprietary software called ePlan. This will mean that the entire Plan will be electronic and revised on a continual basis making the Plan current all the time. Administratively, the Plan will be part of the corporate IMS System.

Response to SIR-1.42

DEQ Request:

(xii) noise, radio, and television interference and electric effects

SIR-1.42: How many residences are located within 500 feet of the associated power lines? Would noise, radio, and television interference, and electrical effects be an issue?

Keystone Response:

See revised Attachment O for the number of residences within 500 feet of the alternative power line routes.

Power Provider Practices – Routing and siting information related to electromagnetic and inductive mitigation on the 115 kV power lines and radio communication serving the Keystone XL Pipeline is provided below.

Electromagnetic induction does occur from power lines. The potential radio and television interference, as well as, noise interference, is mitigated by keeping the power line located away from residences (500 feet minimum, if possible). The routing of the power line is done to keep parallel metallic plant (pipelines, metallic cable, fences) at a minimum. On fences, when paralleling the power line, the metallic wire is grounded (driven ground electrode) at least four times per mile. When crossing fences, the metallic wire is grounded using a 5 foot (minimum) ground electrode. Whenever possible a 100 foot right-of-way for the 115 kV power line will be obtained to minimize any future installation of facilities that could be affected by induction.

There are three potential influences on a communication (metallic) plant in the vicinity of a power line. These are inductive influence, coupling, and susceptiveness. The power providers will work closely with sister utilities to determine the route of existing cable plant. Routing takes into account other utilities and keeps separation between the two different types of plant. Montana state law requires that the project engineer obtain as-built information from other utilities. This allows the design engineer the ability to mitigate inductive influences, to the best of their ability. Avoiding paralleling facilities for long distances (over ten miles) is one method of reducing the susceptiveness to communication plant. Shielded telephone cables reduce coupling with nearby power lines. This helps to reduce coupling caused by close spacings.

Harmonic and waveform distortion may occur due to rectifier action of solid-state motor speed controllers. Harmonic mitigation measures are required on all large loads. Experience with the Express Pipeline indicates that when the harmonic filters tripped off line, noise built to levels that effectively shut down the telephone communications. Close cooperation between the consumers (large motor loads) and the power providers will mitigate such harmonic potential. Harmonic filters will be required, based upon measured system harmonic influence levels.

No impacts are expected from the radio communication systems at the Project facilities with regards to electrical and magnetic fields. The only electromagnetic field emitted from the radio antenna is the normal radio frequency signal as licensed by the FCC.

The C-filter on communication systems eliminates the 60 Hz induced noise, but not the harmonics on a telephone system. The system is terminated in delta – wye configurations. This keeps the phase currents relatively balanced. Mitigation efforts on the distribution circuits will include phase balancing.

Power line Radio Frequency Interference (RFI) is usually caused by sparking (arcs). Typically this is caused by loose hardware.

Power lines associated with the Project will have with similar specifications as those analyzed for the Bonneville Power Administration EIS for the construction of a 115 kV circuit from Libby to Troy, Montana (BPA

Keystone XL Project – Montana Major Facility Siting Act Application

2008). The cooperative's proposed electric service facilities for the Keystone XL pipeline will be nearly identical to the BPA single-pole construction. For their transmission line, BPA calculated typical magnetic and electric field strengths. Because no national standards for EMF are in place, industry practice is to limit EMF exposure at or below those in a typical house. As shown in the following figure, at 40 feet from the power centerline, the electric and magnetic field levels calculated for that 115 kV transmission line are equal to or less than this level; therefore, based on power lines with similar specifications, EMF levels will be at or below acceptable values at 40 feet from the transmission centerline. If required by DEQ, the cooperatives can commit to calculate the EMF fields using the BPA Corona and Field Effects Program (USDOE).

2008. Bonneville Power Administration (BPA). 2008. Rebuild of the Libby (FEC) to Troy Section of Bonneville Power Administration's Libby to Bonners Ferry 115-kilovolt Transmission Line Project; Final Environmental Impact Statement. DOE/EIS - 0379. May 2008.

As stated in the Clarification for Section 3.6(7)(c), every effort is made to maintain a minimum clearance of 500 feet to the extent practical, but never less than 100 feet at these locations. Maintaining a minimum of 100 feet from residences will ensure there will be no EMF effects noticed by residents within their homes.

The power provider design uses spring washers to keep hardware tight. Conductor supports use trunion clamps and AGS factory preformed clamps to keep the conductor and support clamps with a firm contact between the two entities at all times, to mitigate arcing sources. At the 115 kV level, corona is usually not a major issue. Corona in itself is not a major source of RFI. Defective lightning arrestors also contribute to RFI. The power providers use a static conductor at the top of the pole to mitigate lightning caused flashovers. Lightning arrestors are limited to the stations where major equipment is located.

These are some of the measures that are incorporated in the line design to minimize the inductive and noise causing potential to communication and other affected facilities.

The radio communication systems at the Project Facilities will operate on specific frequencies licensed by the FCC. This minimizes the risk of any interference with radio, television or any other communication system in the area as well as providing for a process if any interference should occur.

Keystone XL Project – Montana Major Facility Siting Act Application

Response to SIR-1.43

DEQ Request:

SIR-1.43: Text on page 4-181, section 4.5.1.6 says one of the avoidance areas was state land. For what reason did you avoid state land?

Keystone Response:

The reference to avoiding state land was inadvertently included in the paragraph in question. A significant amount of state lands are crossed by the proposed routes. Consistent with MCA 75-20-301(1)(h), the use of public lands for the location of the facility was evaluated by Keystone, and public lands were selected where their use was as economically practicable as the use of private lands. Routing was developed through processes identified in Section 4.0. Public lands were crossed by route alternatives; however, consistent with the “economically practicable” provision, preferentially crossing public lands for the sole purpose of maximizing presence on these lands was considered to be less crucial than producing the most constructible and direct route. Crossing public lands in some areas offered more potential for environmental effects or constructability issues, or resulted in a longer route. Therefore, in these cases, opportunities to avoid private lands by ‘stitching’ across public lands were not preferable.

While Keystone believes it has appropriately considered public lands in route development, at DOS and MDEQ’s request, Keystone has generated additional alternatives using a GIS model and associated data layers as outlined in DOS DR #1. These alternatives along with the previous alternatives were reevaluated utilizing the same level of data on each route alternative so an equal comparison was made to each alternative and the preferred route selected. This information was provided to MDEQ August 17, 2009.

Clarification for Section 3.8(1)(i)

DEQ Request:

- (i) Overlay to map and electronic equivalent required by section 3.6(2) indicating discharge points.

Specified discharge points for hydrostatic discharges were not listed nor were landowners, water supply wells, and the information describing existing ground water quality and uses within 1 miles of the discharge.

Keystone Response:

Table 1: Potential Sites for Discharge of Hydrostatic Test Water in Montana, provides a listing of probable areas for dewatering. These locations are based on best available information at this time. Final dewatering locations will be determined once the hydrostatic test contractor is selected and presents a hydrostatic test plan to Keystone. **Table 2:** Wells, Ground Water Quality and Water Uses within One Mile of Potential Hydrostatic Test Dewatering Locations, provides water supply wells within one mile of sites. It also provides information on ground water quality and groundwater uses where available. Keystone submits that data provided herewith should be adequate to justify a completeness determination with respect to this item.

Following **Table 2** are two sets of ground water quality reports. The ground water quality well identification numbers listed in **Table 2** were entered into web databases and the reports downloaded where available. Where groundwater quality reports are available, these wells are in bold and italics in **Table 2**. USGS ground water quality reports are first and the Montana Groundwater Information Center (GWIC) water quality reports follow. Where specific ground water quality data is not available, it has been more generally discussed in Chapter 4, Section 4.3.5 of the KXL MFSA application.

Background:

In order to create **Table 2**, the following data sets were downloaded:

Point of Diversion (POD) wells and Water Rights - Place of Use (POU) data was available from the Montana Department of Natural Resources and Conservation: Water Resources Division. Data were downloaded from: <ftp://nris.mt.gov/dnrc/>

Well information was downloaded from a number of sources:

National Water Information System (NWIS) wells were downloaded from a web database with latitude/longitude and converted into a shapefile: http://waterdata.usgs.gov/nwis/gw#top_of_page

GWIC well data was downloaded from: <http://nris.mt.gov/nsdi/nris/shape/gwicwells.zip>

Other wells were downloaded for a web database by downloading by county, combining tables and converting into a shapefile. This site has well data from several agencies: <http://nris.mt.gov/Apps/WQProject/watermain.asp>

USGS Groundwater quality reports were downloaded from: http://waterdata.usgs.gov/mt/nwis/annual?referred_module=gw&search_criteria=search_site_no&search_criteria=site_tp_cd&submitted_form=introduction

GWIC ground water quality reports were downloaded from: <http://mbmggwic.mtech.edu/sqlserver/v11/help/go/signin.asp>

Note: There is little groundwater information available for Routes A and A1A due to the high porosity of underlying strata. Groundwater along both of these routes will likely be found very deep and it is unlikely that aquifers are present due to high porosity. Discharge of hydrostatic test water shall be conducted at least a half mile from all streams to allow for recharge. However, if dewatering is conducted too far from the source it will filter down into the groundwater table. A buffer will be needed to allow for test water to seep into the ground and recharge adjacent streams. The discharge of test water will be left to the discretion of the Environmental Inspector.

Note: Well ID numbers in bold and italics indicate those wells for which groundwater quality reports are available from USGS and/or GWIC. These reports follow Table 2.

USGS Ground Water Quality Reports

File created on 2009-05-11 13:26:58 EDT

U.S. Geological Survey

This file contains selected water-quality data for stations in the National Water Information System water-quality database. Explanation of codes found in this file are followed by the retrieved data.

The data you have secured from the USGS NWISWeb database may include data that have not received Director's approval and as such are provisional and subject to revision.

The data are released on the condition that neither the USGS nor the United States Government may be held liable for any damages resulting from its authorized or unauthorized use.

To view additional data-quality attributes, output the results using these options: one result per row, expanded attributes. Additional precautions are at: <http://waterdata.usgs.gov/nwis/qwdata?help>

						Zirconium (Zr):	NR

Field Chemistry and Other Analytical Results

**Total Dissolved Solids (mg/L): 1,562.300		Field Hardness as CaCO3 (mg/L):	NR	Ammonia (mg/L):	NR
**Sum of Diss. Constituents (mg/L): 2,166.600		Hardness as CaCO3: 61.500		T.P. Hydrocarbons (µg/L): NR	
Field Conductivity (µmhos):	2350	Field Alkalinity as CaCO3 (mg/L):	NR	PCP (µg/L): NR	
Lab Conductivity (µmhos):	2321	Alkalinity as CaCO3 (mg/L): 976.82		Phosphate, TD (mg/L as P): NR	
Field pH:	NR	Ryznar Stability Index: 6.933		Field Nitrate (mg/L): NR	
Lab pH:	8.15	Sodium Adsorption Ratio: 32.402		Field Dissolved O2 (mg/L): NR	
Water Temp (°C):	10.5	Langlier Saturation Index: 0.608		Field Chloride (mg/L): NR	
Air Temp (°C):	NR	Nitrite (mg/L as N): NR		Field Redox (mV): NR	
		Hydroxide (mg/L as OH): NR			

Notes

Sample Condition: SHALLOW GW 048*WATER WAS BROWN*

Field Remarks:

Lab Remarks:

Explanation: mg/L = milligrams per Liter; µg/L = micrograms per Liter; ft = feet; NR = No Reading in GWIC

Qualifiers: A = Hydride atomic absorption; E = Estimated due to interference; H = Exceeded holding time; K = Na+K combined; N = Spiked sample recovery not within control limits; P = Preserved sample; S = Method of standard additions; * = Duplicate analysis not within control limits; ** = Sum of Dissolved Constituents is the sum of major cations (Na, Ca, K, Mg, Mn, Fe) and anions (HCO3, CO3, SO4, Cl, SiO2, NO3, F) in mg/L. Total Dissolved Solids is reported as equivalent weight of evaporation residue.

Disclaimer

These data represent the contents of the GWIC databases at the Montana Bureau of Mines and Geology at the time and date of the retrieval. The information is considered unpublished and is subject to correction and review on a daily basis. The Bureau warrants the accurate transmission of the data to the original end user. Retransmission of the data to other users is discouraged and the Bureau claims no responsibility if the material is retransmitted.

-------------------	-------	-----------------------	------

Notes

Sample Condition:

Field Remarks: NGP-307 * FLOWING WELL * SAMPLE TAKEN IN BARN AFTER SUB. PUMP AND TANK * WELL SOUTH OF HOUSE AND BARN *

Lab Remarks:

Explanation: mg/L = milligrams per Liter; µg/L = micrograms per Liter; ft = feet; NR = No Reading in GWIC

Qualifiers: A = Hydride atomic absorption; E = Estimated due to interference; H = Exceeded holding time; K = Na+K combined; N = Spiked sample recovery not within control limits; P = Preserved sample; S = Method of standard additions; * = Duplicate analysis not within control limits; ** = Sum of Dissolved Constituents is the sum of major cations (Na, Ca, K, Mg, Mn, Fe) and anions (HCO₃, CO₃, SO₄, Cl, SiO₂, NO₃, F) in mg/L. Total Dissolved Solids is reported as equivalent weight of evaporation residue.

Table 2	Bald Eagle Winter Roost Survey Results – Keystone XL Project – February 2009	6

Executive Summary

An aerial survey was conducted along the Montana portion of the Steele City Segment of the TransCanada Keystone Pipeline, L.P. (Keystone) XL Project (Project) Right-of-Way (ROW) on February 11, 2009, to identify bald eagle winter roost sites. The aerial surveys were conducted in a helicopter with a pilot and a 2-person survey team. The surveys covered an area at least 1 mile upstream and downstream of major waterbody crossings and within all suitable bald eagle nest and winter roost habitat.

Three bald eagle winter roost sites were observed within the proposed ROW in Montana along the Yellowstone River, Missouri River, and Frenchman Reservoir. No active bald eagle nest sites were identified during the surveys but one potential bald eagle nest was located within 1 mile of the ROW at the Missouri River crossing.

Introduction

Keystone is proposing to construct and operate a crude oil pipeline and related facilities from Hardisty, Alberta, Canada, to the Port Arthur and east Houston areas of Texas in the United States (US). The Project will have a capacity to deliver up to 900,000 barrels per day of crude oil from an oil supply hub near Hardisty to existing terminals in Nederland near Port Arthur and the Houston Ship Channel in Houston, Texas. The Steele City Segment extends from Hardisty, Alberta, southeast to Steele City, Nebraska. The Gulf Coast Segment extends from Cushing, Oklahoma, south to Nederland, Texas. The Houston Lateral extends from the Gulf Coast Segment, Liberty County, Texas, southwest to Moore Junction, Harris County, Texas. In total, the Project will consist of approximately 1,707 miles of new, 36-inch-diameter pipeline, consisting of about 327 miles in Canada and 1,380 miles within the US. It will interconnect with the northern and southern termini of the previously approved 298-mile-long, 36-inch-diameter Keystone Cushing Extension segment of the Keystone Pipeline Project. The Project is planned to be placed into service in phases. The Gulf Coast segment is planned to be in service by the second quarter of 2011 and the Steele City Segment and Houston Lateral are planned to be in service in 2012.

Background Information

Effective August 8, 2007, the bald eagle was removed from the list of federal threatened or endangered species in the lower 48 states (72 Federal Register 37345). The Department of State has no further requirement to consult on the bald eagle under Section 7. However, the bald eagle remains a species of concern in Montana.

Bald eagles also are protected under the Bald and Golden Eagle Protection Act (BGEPA) and the Migratory Bird Treaty Act (MBTA). The BGEPA not only protects eagles, their young, eggs, and active nests as the MBTA does, it also protects eagles from harm and harassment. "Take" under the BGEPA is defined as to pursue, shoot, shoot at, poison, kill, capture, trap, collect, molest, or disturb. Because bald and golden eagles are afforded more protection than birds protected solely under the MBTA, there was a need to conduct these surveys in order to assess Project-related impacts to the species.

Bald eagles use mature, forested, riparian areas near rivers, streams, lakes, wetlands, and reservoirs. They nest, migrate, and winter in all three states and within most of the counties along the Project route. They generally nest from early February through mid-August, and often return to use the same nest and winter roost year after year. The bald eagle's diet consists mostly of fish. Eagles also forage opportunistically on waterfowl, dead fish, jackrabbits, and big game carrion – especially in winter.

Southward migration begins as early as October, and the wintering period extends from December to March.

Methods

Federal and state agencies were consulted on the location of historic communal roost sites along the Project route prior to the surveys. A historic communal roost site is located on the Missouri River near the School Trust Fishing Access Site, approximately 2 miles upstream of the proposed Missouri River crossing (Bureau of Land Management [BLM] 2009; Montana Fish, Wildlife, and Parks 2009).

The 2009 aerial bald eagle winter roost survey focused on locating bald eagle winter roost sites along major waterbodies within 1 mile of the Project. Aerial survey methods for the 2009 surveys followed those outlined by Call (1978). Two surveyors (seated in left- and right-hand positions of the helicopter) examined suitable habitat within 1 mile (on each side) of the centerline. Prior to initiating the survey, the most up-to-date centerline track for the pipeline was downloaded onto the helicopter's global positioning system (GPS) unit. Aircraft navigation along the proposed pipeline ROW and maintenance of appropriate aircraft position in relation to the ROW was then facilitated using a pilot-operated and monitored GPS unit. Aircraft position and location along the ROW was further monitored by the rear, right-hand observer using a separate GPS unit that displayed real time position. Aerial maps also were utilized by the front, left-hand observer to make notes on features observed.

The February 11, 2009 survey started at the southern border of Montana in Fallon County and proceeded northward to the northern terminus in Phillips County.

Surveys were conducted between sunrise and sunset (approximately 0730 to 1730 Central Time). The date, temperature, wind, and cloud cover were recorded at the beginning of each survey day and at the end of each survey day; changes in overall weather conditions during the survey also were recorded.

Temperatures during the survey ranged from highs of approximately 60 degrees Fahrenheit (°F) to lows of 27°F. Skies were generally clear to partly cloudy with little to no precipitation. Winds were inconsistent, ranging from 15 to 40 mph out of the Northwest during the survey period.

Complete coverage of the entire ROW was obtained by traveling down the centerline and visually scanning all areas of potential bald eagle nesting and winter roost habitat. This typically involved slowing aircraft speed to 25 to 40 mph within the vicinity of waterbody and riparian areas. All perennial rivers crossed by the ROW were initially selected as potential areas to be searched for bald eagle winter roosting activity (**Table 1**). However, during the February 2009 aerial survey, a number of these crossings were determined not to support suitable bald eagle winter roosting habitat, either because the river was completely frozen over and there was no open water for bald eagle foraging and/or there were no suitably sized roost trees along the river within 1 mile of the ROW (**Table 1**). At major river crossings where suitable bald eagle winter roosting habitat (large trees and open water) was present, a 2-mile survey corridor centered on the ROW was obtained by flying 1 mile from the ROW centerline along one side of the river and returning along the opposite side of the river to the ROW centerline. The same process was then repeated on the opposite side of the ROW. Only raptor nests large enough to support eagle nesting activity were recorded within 1 mile of the ROW centerline. The observers also noted and recorded perched bald eagles in trees as well as bald eagles flying along the river corridor. GPS location coordinates were recorded for all bald eagle roost and nest sites observed. In addition, general GPS coordinates were recorded for areas along the river where bald eagles were observed in flight. General observations on bald eagle behavior and numbers also were recorded where birds were observed. Once a bald eagle was located, a second pass-over was made to confirm the use of the site, and to obtain

accurate GPS location coordinates using the front observer's GPS unit. Observers recorded notes on habitat, activity, and nearest pipeline milepost.

Initially, the focus of the bald eagle roosting portion of the surveys was to survey major river crossings either early in the morning (within an hour after sunrise) or late in the afternoon (1 hour before sunset) when eagles were most likely to be found using nighttime roost sites. However, as the survey progressed, it was noted that bald eagles were observed along the major rivers during most of the day, signifying the importance of the site to nesting, roosting, or foraging activities. In addition, it also was noted that bald eagles often flushed from perch sites as the helicopter flew into the vicinity making accurate identification of specific roosts difficult. As a result, survey emphasis shifted to recording bald eagle presence rather than specific roost trees although eagle perch site locations were still recorded. It was assumed that if bald eagles were located within 1 mile of the ROW, then nighttime roost sites likely also were present within 1 mile of the ROW.

Results

Bald Eagle Winter Roost and Nest Sites

The USFWS defines two types of bald eagle winter roost sites. Transitory roosts are described as sites with 3 or more eagles, within 100 meters of each other, for at least 2 nights in an area with no previous history of winter communal roosting. Communal roosts are defined as six or more eagles in a small area for extended periods of time or used for multiple years. Since a one-time winter aerial survey cannot distinguish between transitory roosts versus communal roosts, it was assumed that if bald eagles were observed perching along a river within 1 mile of the ROW, then at least some type of roosting activity occurs within 1 mile of the ROW. Follow-up ground surveys would be required to determine if identified roosting areas represent transitory or communal roost sites.

Out of the 20 perennial waterbody crossings initially selected as survey locations for bald eagle winter roost areas within the vicinity of the Project in Montana, 17 were found to be frozen solid and/or supported no suitable-sized perch trees near the proposed ROW. These river crossings were eliminated from further surveys for bald eagle winter roosting use (**Table 1**). Bald eagles and bald eagle perch/roost trees were recorded at three waterbodies either crossed or approached by the ROW in Montana. These waterbodies included Frenchmen Creek, the Missouri River, and the Yellowstone River (**Table 2**). In addition, a potential eagle nest was located 0.6 mile west of the ROW crossing of the Missouri River.

Discussion

The intent of the February 2009 aerial surveys was to identify bald eagle winter roost locations within 1 mile of the proposed pipeline ROW. The data will aid in project planning in two ways: 1) provide information to avoid the disturbance roost sites located within the construction ROW during the winter roost period, and 2) provide historic roost location information for specific follow-up surveys that may need to be completed to determine activity status immediately prior to construction. Follow-up surveys will be conducted at major waterbody crossings with documented eagle activity to confirm the location of transitory or communal winter roost sites, if pipeline construction will occur at any of these crossings between October 1 and January 31. Winter roost surveys will be conducted at least 1 day prior to the first date of construction.

Keystone is confident that the data provided in this report and for the 2009 survey will be sufficient for project planning and application of appropriate mitigation measures, if warranted. The next important step in the protection of bald eagle winter roosts from construction and operation will be consultation with the

USFWS, BLM, and Montana Fish, Wildlife and Parks, and the development of an agency approved mitigation plan and implementation process.

Mitigation Planning

The data from these surveys will allow Keystone and appropriate wildlife agencies to plan construction along the ROW to avoid the disturbance of roosting bald eagles, where possible. Bald eagle winter roost surveys were conducted during the 2009 winter roosting period to obtain complete coverage for the ROW. However, mainline construction currently is proposed to commence in 2011. It is likely that activity status of roost sites will change in the interim between survey completion and pipeline construction in 2011. It is Keystone's intent to minimize impacts to wildlife species, including roosting eagles; therefore, all attempts will be made to construct during periods with the least impact to wintering birds. In the event that construction occurs during the roosting season, it may be necessary to provide a biological monitor or clearance surveys along certain portions of the route that would be scheduled for construction between October 1 and January 31 to prevent disturbance to wintering bald eagles. However, these measures would depend on a number of site-specific factors and would be determined on a case-by-case basis with the applicable agencies.

It is anticipated that areas that would be disturbed by construction would be resurveyed prior to commencement of construction activities, or a biological monitor would be present to determine whether wintering bald eagles could be affected by project activities. Based on these survey results, Keystone would coordinate with the applicable agencies to determine whether additional protection measures may be warranted. It is possible that construction could proceed in certain areas near known roost sites depending the distance between construction and the roost site, line-of-sight implications between the roost site and construction activities, duration and type of construction activity, and/or the presence of a qualified biologist to monitor bird behavior and response to construction activity.

Table B-1	Raptor Nest Survey Results – Keystone XL Project – 2009 Aerial Surveys – Route B
Table B-2	Raptor Nest Survey Results – Keystone XL Project – 2009 Aerial Surveys – Route A
Table B-3	Raptor Nest Survey Results – Keystone XL Project – 2009 Aerial Surveys – Route A1A

Executive Summary

Aerial surveys were conducted along the Montana portion of the Steele City Segment of the proposed TransCanada Keystone Pipeline, LP (Keystone) XL Project (Project) right-of-way (ROW) between April 15 and April 21, 2009, to identify greater sage grouse (*Centrocercus urophasianus*)/sharp-tailed grouse (*Tympanuchus phasianellus jamesi*) lek sites and raptor nest sites. Additionally, two alternative routes (Routes A and A1A) were surveyed in compliance with the Montana Major Facilities Siting Act.

Raptor Nest Surveys

One aerial survey was previously completed to collect raptor nest occurrence information along the Steele City Segment of the proposed Project ROW from April 7 through April 10, 2008 (Keystone 2008). This report covers a second additional raptor nest aerial survey conducted along the Montana portion of the Steele City Segment of the Project ROW in addition to greater sage grouse and sharp-tailed grouse lek surveys. All aerial surveys were conducted in a helicopter with a pilot and a 2-person survey team. Based on agency recommendations, the 2008 surveys covered an area of at least 0.25 mile on each side of the proposed ROW alignment. The 2009 survey addressed a 1.0 mile corridor (at least 0.5 mile) on each side of the proposed ROW alignment in Montana based on recommendations provided by Montana Fish, Wildlife, and Parks (MFWP) (AECOM 2008). At major river crossings, survey coverage was expanded to 1 mile on each side of the ROW to search for bald eagle nest sites.

The 2009 survey documented 171 raptor nests in Montana. Additionally, one great blue heron rookery was identified during the surveys.

Greater Sage Grouse/Sharp-tailed Grouse Lek Surveys

Surveys for greater sage grouse and sharp-tailed grouse leks were conducted within suitable habitat along the entire Project route through Montana. Surveys addressed greater sage grouse habitat within 0.6 mile on each side of the proposed ROW. No active greater sage grouse or sharp-tailed grouse lek sites were identified in Montana.

Introduction

Keystone is proposing to construct and operate a crude oil pipeline and related facilities from Hardisty, Alberta, Canada, to the Port Arthur and east Houston areas of Texas in the US. The Project will have a capacity to deliver up to 900,000 barrels per day of crude oil from an oil supply hub near Hardisty to existing terminals in Nederland near Port Arthur and the Houston Ship Channel in Houston, Texas. The Steele City Segment extends from Hardisty, Alberta, southeast to Steele City, Nebraska. The Gulf Coast Segment extends from Cushing, Oklahoma, south to Nederland, Texas. The Houston Lateral extends from the Gulf Coast Segment, Liberty County, Texas, southwest to Moore Junction, Harris County, Texas. In total, the Project will consist of approximately 1,707 miles of new, 36-inch-diameter pipeline, consisting of about 327 miles in Canada and 1,380 miles within the US. It will interconnect with the northern and southern termini of the previously approved 298-mile-long, 36-inch-diameter Keystone Cushing Extension segment of the Keystone Pipeline Project. The Project is planned to be placed into service in phases. The Gulf Coast segment is planned to be in service by the second quarter of 2011 and the Steele City Segment and Houston Lateral are planned to be in service in 2012.

Background Information

Prior to the 2009 aerial surveys, Keystone representatives consulted with federal and state wildlife agencies in a series of meetings, telephone calls, and email conversations regarding appropriate survey protocols for raptors and grouse species. The results of these consultations are found in **Appendix A**.

Raptor Nest Surveys

A variety of raptor species are known to nest in the region of the proposed Project. These species include eagles, buteos, falcons, owls, harriers, osprey, and other birds of prey. Breeding and nest building/tending activities can begin as early as February for some raptor species, and the rearing of young and fledgling dependency can last into early August for some of the later nesting species. Protected raptor species occurring along the proposed route include the bald eagle and the peregrine falcon. Other raptors identified as species of special concern include the ferruginous hawk, Swainson's hawk, and burrowing owl.

Greater Sage Grouse/Sharp-tailed Grouse Lek Surveys

Greater sage grouse surveys have been required by the Bureau of Land Management (BLM) and recommended by the MFWP to assess potential impacts to this BLM-sensitive species and Montana Species of Concern as a result of the implementation of the proposed Project. Additionally, incidental surveys for the plains sharp-tailed grouse were recommended during consultation. Sage grouse occur within sagebrush grasslands of the project area. Sharp-tailed grouse are found with grasslands interspersed with shrub and brush-filled coulees. Both are considered lekking birds and utilize sensitive strutting grounds or lek sites for breeding activities. Breeding typically occurs from March 15 to May 15, with nesting and brooding possibly extending to June 15.

Methods

Aerial survey methods followed those outlined by Call (1978). Two surveyors (seated in left- and right-hand positions of the helicopter) examined the area within 0.6 mile of the Project centerline along the entire ROW in Montana to locate lek sites and existing raptor nest sites. Additionally, a 2-mile buffer was surveyed around proposed pump station locations for lek sites, and a 1-mile area on each side of the ROW was surveyed to locate potential bald eagle nest sites where the ROW intercepted major river crossings. Prior to initiating the survey, the most up-to-date centerline (i.e., the February 15, 2009, version) track for the routes was downloaded into the helicopter's global positioning system (GPS) unit. Aircraft navigation along the proposed pipeline ROW and maintenance of appropriate aircraft position in relation to the ROW was then facilitated using a pilot operated and monitored GPS unit and real time GPS tracking with an on-board computer. Aircraft position and location along the survey corridor was further monitored by the rear, right-hand observer using a separate GPS unit that displayed real time position and the ROW centerline on digital raster graphic (DRG) 7.5-minute US Geological Survey topographic maps. In addition, raptor nest sites identified during the 2008 aerial surveys and historic greater sage-grouse lek sites provided by MFWP (MFWP 2008) were plotted onto 1:24,000 scale aerial maps and downloaded on the DRG topographic maps.

Raptor Nest Surveys

The 2009 aerial raptor survey focused on locating raptor nests constructed in trees in riparian zones, shelterbelts, and other wooded areas and areas of cliffs, rock outcrops, knolls, and other topographic features suitable for raptor nesting. Surveys were conducted in April, which facilitated locating nests in deciduous trees prior to leaf-out and the open terrain facilitated locating ferruginous hawk ground nests. The surveys started at the southern terminus of the Montana portion of the Steele City Segment in Fallon County and continued northwest to the Canadian border. Surveys then proceeded along alternative routes A and A1A.

Surveys were conducted between sunrise and sunset (approximately 0600 to 2000 Central and Mountain Standard Time). Temperatures during the survey ranged from highs of approximately 60 degrees Fahrenheit (°F) to lows of 32°F. Skies ranged from clear to cloudy with little precipitation. Winds shifted from southeast to west/northwest and ranged from 0 to 15 miles per hour (mph) during most of the survey period.

Complete coverage of the survey corridor along the entire ROW was obtained by traveling down the ROW centerline and visually scanning all areas of potential nesting habitat. This typically involved slowing aircraft speed to 25 to 40 mph when woodlands, shelterbelts, riparian areas, isolated trees, cliffs, or rock outcrops were encountered. Once a possible nest site was located, a second pass-over was made to confirm nest type and condition, and to obtain accurate GPS location coordinates using the front observer's GPS unit. Observers recorded notes on nest configuration, condition, possible species, habitat, and nearest pipeline milepost (MP).

The habitat surrounding all waterbodies crossed by the proposed ROW was surveyed for bald eagle nesting activity. At major river crossings where suitable bald eagle nesting habitat (large trees and open water) was present, a 2-mile survey corridor, centered on the ROW, was conducted by first flying 1 mile from the ROW centerline along one side of the river and returning along the opposite side of the river back to the ROW centerline. The same process was then repeated along the river on the opposite side of the ROW. The observers noted and recorded perched bald eagles in trees as well as bald eagles flying along the river corridor. GPS location coordinates were recorded for all bald eagle nest and roost sites observed. In addition, general GPS coordinates were recorded for areas along the river where bald eagles were observed in flight. General observations on bald eagle behavior and numbers also were recorded where birds were observed.

Greater Sage-Grouse/Sharp-tailed Grouse Lek Surveys

Surveys for lek sites followed the protocol established between Keystone, the BLM, and MFWP (AECOM 2009a,b) along the entire route in Montana, including 11 proposed pump station sites. Surveys were conducted from 0.5 hour before sunrise to 2 hours after sunrise unless it was overcast or birds were still active, in which case the surveys were extended. A distance of 0.6 mile on each side of the proposed centerline (1.2-mile survey corridor) was surveyed. This involved flying two transects at 0.6 mile apart (one 0.6 mile to the east of the centerline and one on centerline to survey 0.6 mile to the west). Surveys were conducted within a 2-mile radius (8 transects each 4 miles long at 0.5 mile apart) of each pump station location. In addition, any historic lek sites identified on the 1:24,000 aerial map books were surveyed to verify activity. The survey corridor was established based on current greater sage grouse mitigation measures and based on Keystone's original plan to construct outside the entire nesting period (i.e., after June 15) along the survey corridor in Montana. Should Keystone construct prior to June 15, MFWP recommends using a survey corridor of 4 miles on each side of the centerline and the BLM recommends using a survey corridor of 2 miles on each side of the centerline.

The helicopter was positioned to maximize the sun's early morning horizontal light. Altitude was approximately 100 to 150 feet above the ground, and air speed was from 40 to 70 mph, depending on habitat quality. Altitudes and speeds were adjusted by the observer, as necessary. It was determined that surveys would not be conducted if snow cover was complete (i.e., no open areas), snow depth was greater than 1 inch, precipitation was occurring (snow or rain), or winds were greater than 20 mph. Weather conditions were recorded prior to the start of each survey day.

All sage grouse activity was recorded, including bird behavior, number of birds observed, and females versus males (if possible). Habitat quality was recorded and notes on lek location relative to the overall landscape also were taken, in order to more easily locate the lek in the future. In addition, active lek sites were recorded using a GPS point and mapped on 1:8,000 scale aerial maps.

Results

Raptor Nest Surveys

Appendix B, Tables B-1 through B-3 provides a listing of all nest locations identified during the April 2009 aerial survey. A total of 171 nest sites were documented within the survey area in Montana. Additionally, one great blue heron rookery and three historic raptor nests occupied by Canada geese were identified. Alternative routes A, A1A, and B were surveyed in Montana. Of the 171 raptor nests identified along the alternative routes in Montana, 109 raptor nests were identified along Route B (preferred route), 26 raptor nests along Route A, and 36 raptor nests along Route A1A. **Tables B-1 through B-3** also include universal transverse mercator (UTM) coordinates for each nest location as well as information on species ownership and nest activity (**Tables B-1 through B-3**).

Of the 171 potential raptor nest sites, 51 nests were considered occupied (presence of adults on or around the nest, in incubation posture, or eggs/chicks in the nest). The 51 occupied nests included 15 red-tailed hawks, 12 great horned owls, 2 bald eagles, 4 golden eagles, 17 ferruginous hawks, and 1 prairie falcon. Species ownership determinations for remaining nests were based on nest size, configuration, and location.

Bald eagles were recorded at two major waterbodies along the proposed ROW in Montana (see **Tables B-1 through B-3**). One juvenile eagle was perched at the Yellowstone River crossing. Approximately 10 juvenile and adult eagles were observed roosting on the north shore of the Frenchmen Reservoir to the west of the ROW (see **Tables B-1 through B-3**).

Greater Sage-Grouse/Sharp-tailed Grouse Lek Sites

No active lek sites were recorded within 1.2 miles of the centerline in Montana during the sage grouse surveys.

Discussion

Raptor Nest Surveys

Based on the results of the April 2009 aerial surveys, a number of raptor species breed and forage within and near the Project ROW. The most common species include red-tailed hawks and great-horned owls, with scattered breeding records for the ferruginous hawk, golden eagle, and bald eagle. Given the aerial survey method employed for the Project, nests of some species such as cavity nesters (American kestrel), ground nesters (short-eared owl, burrowing owl, turkey vulture, and northern harrier), and woodland nesters in evergreens (accipiters, long-eared owl, and great horned owl) could not be effectively located. Survey emphasis was placed on locating nests of eagles, buteos, accipiters, and owls that nest in deciduous trees and along cliff formations. These are the most common species that could be affected by construction, particularly if construction were to occur within the breeding season (February through August).

The intent of these surveys was to identify as many raptor nests as possible within or adjacent to the proposed pipeline ROW. The surveys were conducted in anticipation of construction in 2011. Nest data will aid in project planning in two ways: 1) it will provide information to avoid the disturbance of nest sites located within the construction ROW during the breeding season or, if necessary, identify nests that may need to be removed outside of the nesting season; and 2) it will provide historic nest location information for specific follow-up surveys that may need to be completed to determine activity status immediately prior to construction. For the purposes of avoiding adverse impacts to wintering bald eagles, follow-up surveys will be conducted at major waterbody crossings with documented eagle use to confirm the location of transitory or communal winter roost sites, if pipeline construction will occur at any of these crossings between October 1 and January 31.

Greater Sage-Grouse/Sharp-tailed Grouse Lek Sites

Based on the findings of the April 2009 aerial surveys, the Project crosses minimal suitable lekking habitat. Although the survey corridor was determined to be 0.6 mile on either side of the ROW, survey crews confirmed that visibility was actually 1.0 mile on either side of the transects, resulting in a larger survey corridor.

The next important step in the protection of breeding raptors and greater sage grouse/sharp-tailed grouse from construction and operation will be consultation with the USFWS, as well as applicable state game and fish departments, and the development of an agency-approved mitigation plan and implementation process.

Use of GPS

GPS provides an advanced, practical method for precise navigation and to obtain accurate location data, particularly in areas with little to no topographic relief or prominent landmarks. However, use of GPS can occasionally have limitations. Due to wind movement and positioning of the helicopter, GPS coordinate locations could be up to 100 to 200 feet in error from the actual nest location. All efforts were made to obtain the most accurate GPS coordinate locations possible during the aerial surveys. Keystone is confident that the data provided in this report for the April 2009 survey will be sufficient for future lek and nest identification, project planning, and application of appropriate mitigation measures, if warranted.

Issue: Exclusion windows___ Concern Level: High___Moderate_x_Low__.

Description:

Hi Patty,

Our current recommendations for timing exclusions are no surface use or disturbance :

Timing dates: Big game winter range (all): December 1 to March 31
Sharp-tail grouse (within 2 miles of a lek): March 1 to June 15th
Sage grouse (within 4 miles of a lek): March 1 to June 15th
Raptor nests (within 1/2 mile of nest): March 1 to August 1

Windy

To: Smith, T.O. (FWP); Gunderson, Pat; Davis, Windy

Subject: KXL - Information Request - Game Exclusion dates

T.O., Pat, and Windy:

Could you please provide exclusion dates for big game winter ranges and sage / sharp-tailed grouse lek sites? Currently, we are crossing winter range for mule deer, white-tailed deer, and antelope. Windy, I believe you mentioned mid March to late April for the grouse, but just wanted to confirm.

Also, I haven't forgotten about getting you information on the type/amount of habitat crossed by the proposed project. We received an update of the route on July 31st and are running the numbers to correlate with the latest information.

Thank you for your help.

Patti Lorenz

Issue: Sage Grouse Survey Protocol **Concern Level:** High x Moderate Low.

Description:

I called John to discuss the protocol for aerial sage grouse surveys. Modifications were made based on a previous discussion with John Phillips from TROW agreeing not to construct in Montana until after the June 15 breeding/nesting window for sage grouse. Therefore the focus will now be on impacts to actual lek sites with construction activities. The proposed protocol is as follows:

- Aerial surveys will begin on April 15, 2009.
- Within known suitable sagebrush habitat, surveys will be conducted within 0.6 miles (1 km) from the centerline construction corridor. This is approximately the entire route with the exception of Dawson County.
- Surveys will still be conducted within 2 miles (transects flown at half mile apart) at pump stations due to their permanent structure.
- Surveys will be conducted 30 minutes prior to sunrise to 2 hours after sunrise (the exact times will be weather specific).
- The helicopters will be flown between 100 and 500 ft above the ground and between 40 and 70 mph depending

on the habitat quality and specific landowner requests/landuse (i.e., higher for areas with cattle).

- Ground verification of potential lek sites identified from the air will be surveyed pending landowner access to the site.

John concurred with the above protocol but did note that discussion are ongoing about increasing the buffer to 4 miles around permanent structures.

Follow-up Required / Requested**Additional Comments**

Issue: Greater Sage Grouse Survey Protocols **Concern Level:** High X Moderate Low

Description:

Kent called to discuss the survey protocol for the aerial sage grouse lek surveys planned for April 2009. He concurred with the current protocol but would suggest doing three rounds of surveys on future efforts. He also concurred with using staff that is familiar with sage grouse but unfamiliar with aerial surveys as long as a helicopter is being used. Also recommends using the data sheet provided by MFWP.

The following email chain is related to the above telephone conversation:

Hello Patti - i've been meaning to call you for over a week now and things just get busier! Just to clarify things as far as grouse surveys go - are you going to complete aerial surveys within a 4 mile buffer of the proposed line in sagebrush habitat or only a .6 mile buffer (I assume this means 1.2 miles total width) in the sagebrush habitat? I thought your last e-mail in feb. said 4 miles but I might have misinterperated that one. Also there are leks just of the proposed line in mcone county - will the line be moved or mitigated?? Only 1 aerial survey?? I know we probably went over this in the conference call but just making sure. Thanks for your help and feel free to give a call - I do have meetings the next couple days but will

get back to you. I'm also just starting the review of the POD and environ. reports. cheers, kent

Subject
Keystone XL Project - Sage Grouse
Surveys

Kent and Fritz,

I have some great news regarding the KXL Project and sage grouse surveys. I spoke with MFWP and John Carlson last week regarding this update and everyone seemed pretty happy.

The client has agreed not to construct in Montana until after the June 15 breeding/nesting window for sage grouse. Therefore our focus will now be impacts to actual lek sites with construction activities. The proposed protocol is as follows:

Aerial surveys will begin on April 15, 2009.

Within known suitable sagebrush habitat, surveys will be conducted within 0.6 miles (1 km) from the centerline construction corridor. This is approximately the entire route with the exception of Dawson County.

Surveys will still be conducted within 2 miles (transects flown at half mile apart) at pump stations due to their permanent structure. Surveys will be conducted 30 minutes prior to sunrise to 2 hours after sunrise (the exact times will be weather specific).

The helicopters will be flown between 100 and 500 ft above the ground and between 40 and 70 mph depending on the habitat quality and specific landowner requests/landuse (i.e., higher for areas with cattle).

Ground verification of potential lek sites identified from the air will be surveyed pending landowner access to the site.

Please let me know if you concur with this approach. Feel free to give me a call with any questions or comments.

Thanks,

Patti Lorenz, Wildlife Biologist
